The Great Western Automobile Company, of Peru, Indiana, are making a light six-cylinder car upon which a number of claims seem to be of unusual merit. The car combines comfort, convenience and economy and those interested should write to the firm for full particulars.

Magneto With Starting and Oiling System.

The Maxwell Automobile Co. will probably use this season 50,000 of the new Simms high tension magnetos, with the electric starting and oiling system. They decided to install this equipment after making a somewhat extended investigation, and feeling sure of its absolute reliability and satisfaction in every way for car owners. The Simms Magneto Co., will soon have an electric starting and oiling system for the Ford cars on the market. This will give an exceptional opportunity for wide awake dealers and they should write at once for full information, addressing the Simms Magneto Co., East Orange, N. J.

A Gold Mine for The Sears-Cross

Absolutely Accurate. Mounted in a Special New Bracket right before the Driver's Eyes.

THE Sears-Cross Spedindicator was one of the speed meters which were standard equipment on the 1915 Ford car. The Ford car for 1916 will not be equipped with a speedmeter at the Ford factory.

The Sears-Cross Spedindicator, especially made for Ford cars, will be sold by dealers to Ford owners in a special bracket, mounted on the cowl, as shown in the illustration. This bracket places the Spedindicator right before the driver's eyes, where he can read the speed, the total mileage, and the trip mileage at a glance. This does away with bending over to read the speed or mileage, and taking the eyes off the road.

The Sears-Cross Spedindicator set flush in the new special bracket, enables the driver to glimpse the speed or the mileage.

The Fastest Selling Ford Accessory

There are many accessories for Ford cars, but the Sears-Cross Spedindicator is the absolute leader of them all. It opens up a brand new field of profits to Ford dealers and accessory dealers. The new bracket will make the Sears-Cross Spedindicator sell like "hot popcorn" at a county fair.

Don't overlook the really big, quick profits that we offer you. An agency for the Sears-Cross Spedindicator in the new special Ford bracket, is better than a gold mine.

Write or telegraph for our dealer's proposition.

Sears-Cross Company, Bush Terminal, Brooklyn, New York

Sears-Cross Service

Sears-Cross owners are given unusual service. The Sears-Cross Spedindicator stays in service better than any other speed indicating instrument for automobiles. But in the rare cases where replacement of parts or any other form of service is needed, the half-hundred and more Sears-Cross Branches and Sears-Cross Service Stations located so that all parts of the United States and Canada are covered, give quick, efficient service.

A list of Sears-Cross Branches and Sears-Cross Service Stations with their locations follows.

All branches and service stations carry fine stocks of instruments and parts.

Model F 15 (same as used in 1915 Ford cars as regular equipment) Complete, ready to attach, $12.00.
Model FF 16 (as illustrated, new equipment for 1916 Ford cars, flush bracket and longer shaft) Complete, ready to attach, - - - - - - - - - - - - - 15.00.

Atwater Kent

The lifter as it is pulled forward by the notched shaft does not touch the latch, and the contact points remain open.

The lifter, reaching the point where it rolls off the notched shaft is pulled back by the lifter spring, striking the latch as it returns.

The latch, being struck by the lifter, presses against the contact spring and closes the contact points for a brief instant, immediately opening after the lifter passes.

The latch and lifter, having returned to their original position, are ready for the next spark.

The one Ignition System that works on the "open-circuit" principle--as simple and easy to understand as your door-bell or electric-horn.

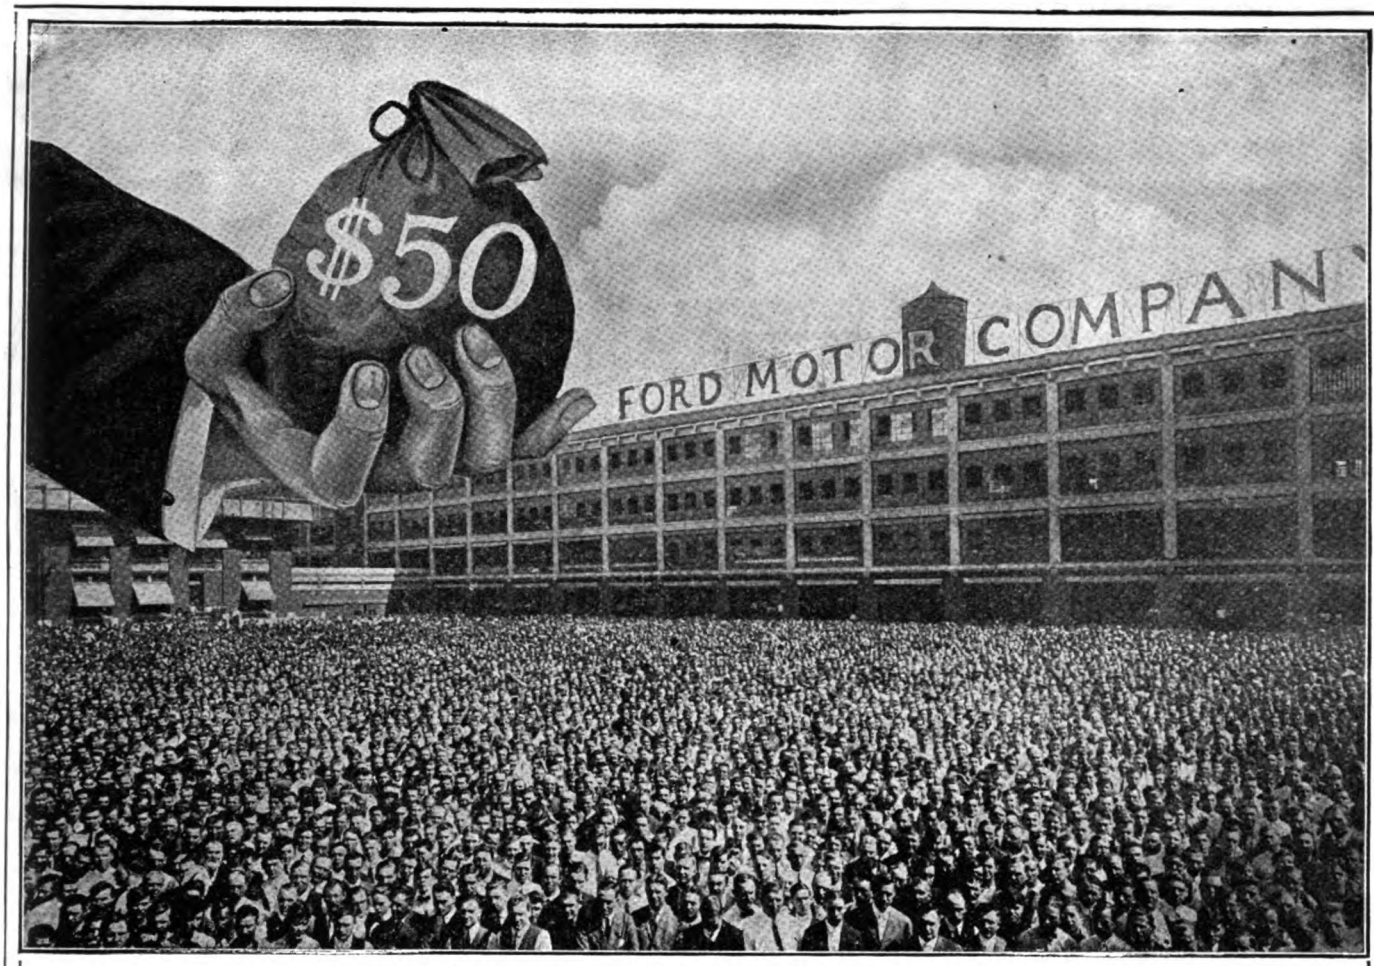
Electricity flows through your door-bell circuit only when someone pushes the button and "closes the circuit" to do the work of ringing the bell.

Now, just imagine in place of the bell a coil which produces a hot spark each time it receives an impulse of current, and in place of the push button, the contact-maker of the Atwater Kent System. You will then understand the principle on which the Atwater Kent System works. By means of the contact-maker the ignition circuit is momentarily closed and instantly opened for each spark.

Owing to the fact that it is impossible to stop the motor in any position which will leave the ignition circuit closed, the Atwater Kent System is fundamentally safe, and no accessory safety devices are necessary to protect the battery. The current flows only during the brief instant of each spark and the ignition switch is practically useless except in stopping the car. In other words, it might be left in the "ON" position permanently without the slightest danger of draining the batteries.

The Atwater Kent principle is absolutely unique among ignition devices. Its success is certified by more than nine years of uninterrupted growth. It is in use to-day on upwards of 200,000 cars and is endorsed by more than 30 reputable manufacturers and over 10,000 dealers, garages and repairmen.

The Atwater Kent magneto replacement system can be easily installed in place of the magneto on any standard car. Thousands upon thousands of car owners, realizing the benefits of Atwater Kent Ignition are installing this system on cars previously equipped with magnetos and other types of ignition.



Our special outfit for Fords deserves the investigation of every owner of this remarkable car, and the opportunities which it offers to dealers, garages and repairmen are attracting the attention of the entire trade.

If you are not fully posted regarding this wonderful system by all means get in touch with us without further delay. You owe it to yourself to have our complete data on file.

Study This Illustration
And See Why
Oil MUST Run Off; Soot CAN'T Form

at the sparking point of this plug. Notice the form of the electrodes—any oil splashed against them must run down and away from the sparking point, just as rain runs away from the ridgepole of a house. This is only one of many unusual features that make

JUMBO SPARK PLUGS

the best buy in the spark plug market. The big, massive insulator will not crack with the heat. A liberally proportioned copper-asbestos washer prevents compression leakage, and protects the porcelain insulator from the hammer-like blows of explosion.

No matter what terminals are on the cables in the car, Jumbo Jiant will fit them, because it has a

Universal Terminal

which gives perfect electrical contact with plain, Q-D or slip terminals. This means that the dealer needs to carry in stock only a third as many plugs to meet all requirements.

When you put a set of Jumbo Jiants on your car, your plug troubles are taken care of for fifty-two weeks, for

Every Jumbo Jiant is Guaranteed For a Year

This means precisely what it says—if, at any time within one year of purchase, a Jumbo Jiant develops any defect, or in any way falls down on the job, you can get a new one without further cost. Just send the defective plug back to us, with the guarantee coupon issued at time of purchase, and we will see that you're supplied with a new plug.

Test Jumbo Jiant For Yourself

If you are a dealer, write us on your own letterhead, and we will send you a plug for trial. Test it out under the most severe conditions you can think of. If it doesn't fully prove its absolute superiority over every other plug made in America, we won't expect your future business.

Our discounts will interest you—write for them

Showing the Variety of Work Handled and Simplicity of Apparatus

Positive Profits—Easily Made by Oxy-Acetylene Welding

Garage owners everywhere are finding this process a ready money-maker.

Parts that seem hopelessly damaged are made good as new—easily, quickly and at small cost. Repairs possible by no other method become simple every-day routine work.

Naturally, this kind of service and the pronounced savings please garage patrons. It brings new customers to your shop. At the most moderate charges, YOUR profits are too large to overlook.

PREST-O-LITE

Dissolved Acetylene

Simplifies—Cheapens and Improves this Process for All Garage Work

Very small outlay for apparatus is required. Equipment soon pays for itself. We furnish a thoroughly high grade welding outfit for $60. The average user will also need gas cylinders at additional cost and about $10 worth of welding supplies. Truck and special cutting equipment at extra cost. Complete instructions free with every outfit.

Prest-O-Lite Acetylene Service furnishes the highest grade of Dissolved Acetylene (ready-made carbide gas) in portable cylinders, used as conveniently as you use cylinders of oxygen. Saves the large initial outlay and heavy depreciation, trouble and inconvenience of making crude Acetylene in carbide generators. Besides, Prest-O-Lite Dissolved Acetylene is perfectly dried, cleaned and purified —makes better welds and is cheaper to use.

START NOW—GET FULL DETAILS.

The demand for Oxy-Acetylene Welding Repair work is large and growing. Get your share of the profits. Send for literature that shows how you can apply Oxy-Acetylene welding in your shop, with profits to you and savings for your customers.

The Prest-O-Lite Co., Inc.,

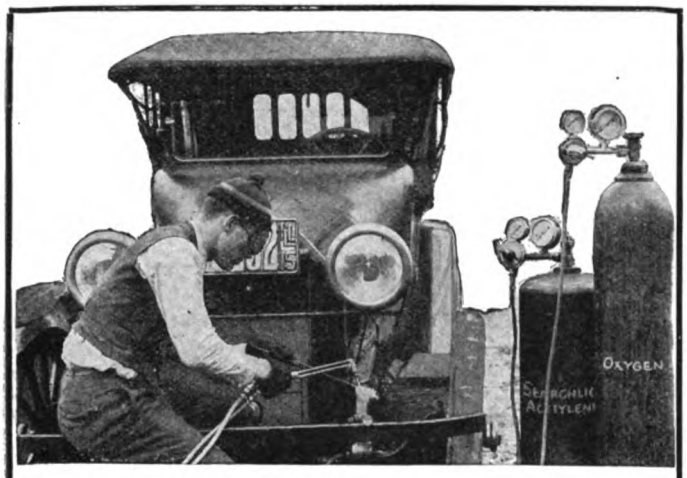
Announcing the AUTOMATIC · IGNITION CONNECTICUT SYSTEM

for FORD Cars

FORD DEALERS
Send for this Book.

It is a magneto mechanism less the current generating unit, but works in just the opposite way—delivering a spark tempered exactly to the motor's requirements—its hottest spark at slowest speeds—giving an increased range of high gear efficiency—hill climbing ability and power for sustained speed never before considered possible in a Ford motor.

Its ideal adaption is in conjunction with a storage battery charged by a generator.



It is simplicity itself and what is better, the most modern and effective system of ignition ever developed.

For information and territory write or wire.

BIG PROFITS IN THIS WORK!

The automobile in the picture run up to the garage with a broken frame. This up-to-date garage with its Searchlight Welder fixed the frame in forty-eight minutes and charged $18.

Repairs that the other fellow can't handle are the ones that make you the big money.

Don't let this profitable business go past your garage to your competitor. There is no apparatus as profitable in a garage as an acetylene Welder.

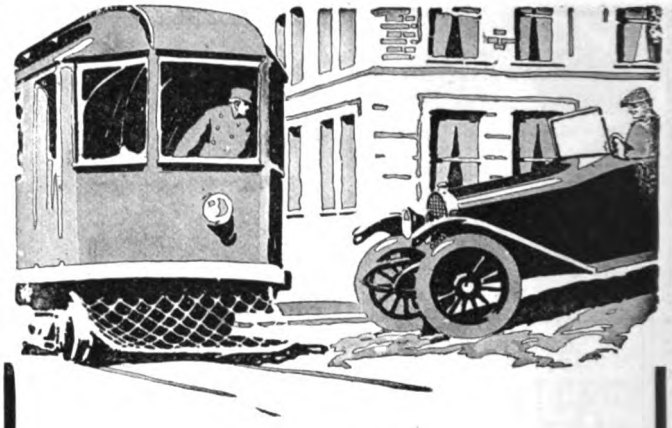
And there is no welder as dependable, economical and easy to operate as the

Searchlight Welder

FOR GARAGES

This is the only welder in its class which sells for less than $100.00.

$50 Cylinders Extra



Fifty dollars is the price for the Searchlight Equipment for garages. More money can't buy a better equipment and it isn't wise to buy a welder for less.

Write for information and we will show you the new source of big profit.

What stopped the automobile in front of your door?

Brake Lining!

There is a constant demand from motor car owners for brake lining, because even the best will not last forever. There is a steady demand for

Thermoid
HYDRAULIC COMPRESSED Brake Lining - 100%

because it is known universally as the brake lining that retains its gripping efficiency until worn paper thin. Thermoid is brake lining clean through—tougher for its purpose than steel itself. It is brought by hydraulic compression to a uniformity and density that give 100% gripping power until it is actually worn out. Even that takes months longer.

You will find it worth your while to look into Thermoid as a motor accessory staple. A line will bring further particulars.

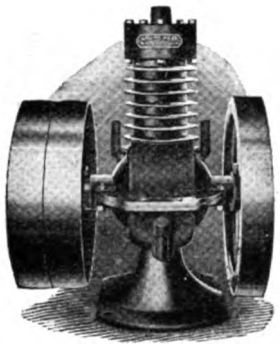
The Main Points

The Au-To Air Compressor is designed especially for automobile garages, electric motor cleaning, water systems, machine shops, foundries and all other purposes requiring not over 6½ or 13 cubic feet of free air per minute at not exceeding 300 lbs. pressure.

The Au-To Air Compressor is built to take care of itself. It is all metal—no leather packing or washers to wear out. It is air-cooled—no freezing, no troublesome tanks, water jackets or pipe connections. The location of the pipes in the crank-case, permitting the fanning process both inside and out, enables the Au-To Air Compressor to develop its remarkable speed and pressure without overheating. Its valves are removable—no secreting of these parts in the base, where pipe connections and foundation joints have to be broken to get at them.



The Au-To Air Compressor is built of the best materials obtainable for the purpose, under the hands of expert machinists. All moving parts are given an ample margin of mass and strength to withstand exceptional strain. Cylinders are made of a special carbon cast iron.

Every Au-To Air Compressor bears this label.

It is your guarantee of efficiency and satisfaction.

Literature on request.

The Au-To Air Compressor

SMALL POWERFUL INEXPENSIVE

The small size and large capacity of the Au-To Air Compressor, combined with its surprisingly low price, have made The Au-To Air Compressor the leader in its line, and have placed it with the leading jobbers in every part of the country.

The Au-To Air Compressor is built to supply 6½ cubic feet of free air per minute at 300 lbs. pressure—occupying a floor space of only 14x18 inches—with all bushings and bearings of finest quality bronze—with crank-shaft and connecting rod of A No. 1 forged steel—with a perfect balance between tight-and-loose pulley and fly-wheel to insure frictionless running and even wear.

Specifications

Power Required—1½ H. P.

Pressure - constant pressure of over 200 pounds without overheating.

Capacity—6½ cubic feet of free air per minute at 400 revolutions.

Crank Shaft, Connecting Rod, Cap } Forged high carbon steel.

Bearings, Bushings } Bronze (Very best grade).

Cylinder—3" bore, single acting.

Piston—4" stroke—3 eccentric rings—2 at one end; 1 at the other end.

Valve—new type—accessible by removal of but five bolts, with no breaking of pipe connections.

Gaskets—best quality asbestos.

Pulleys—tight-and-loose—13" diameter, 2" crown face—weight about 40 lbs.

Fly-Wheel—14" diameter—weight about 40 lbs.—balances pulley and gives absolutely even wear on bearings.

Air Intake—21" above floor (to avoid dust).

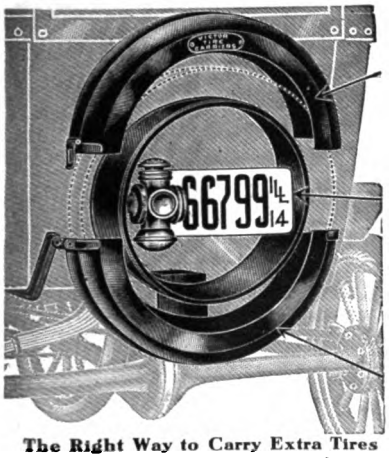
Lubrication—splash.

Height—21" over all.

Floor Space Required—14"x18".

Weight—130 lbs.

Speed Recommended—400 revolutions per minute.



Guaranteed Pressure—300 pounds.

Literature on request.

HEISER'S IMPROVED CYLINDER REBORING TOOL FOR FORD ENGINES

REPAIRMAN

There has been a period in your life that you were unable to tell a valve from a spark plug, a magneto from a carburetor, or a cylinder from a piston; some one had to tell you what these parts were and their function. The troubles arising from these and other parts of a car, you have mastered, but you are still at sea if you do not understand and are not prepared to rebore and fit oversize pistons, for this is the most important repair that can be given a worn engine.

The HEISER IMPROVED CYLINDER REBORING TOOL for Ford Engines, makes a good shop out of a poor one and a better shop out a good one, but best of all, it gives the owner service. The end of this season will see one million Fords on the highways; this means many million dollars will be spent on reboring and fitting oversize pistons.

The early bird catches the worm. We furnish oversize pistons to fit the rebored cylinder, $1.50 each, Complete.

Write for further particulars about this wonderful tool.

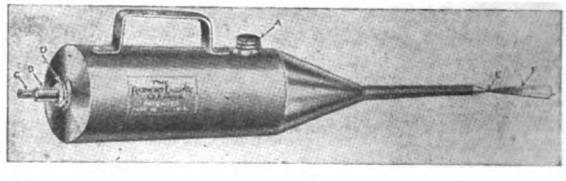
CLEAN OUT THE CARBON WITH STEAM



The Hart-Bell Carbon Remover cleans out the carbon with live steam. It is permanently installed on the intake manifold, and a turn of the handle admits a fine spray of water vapor that is instantly converted into superheated steam by the ignition in the cylinder. The steam loosens the carbon while the motor is running so that in five or ten minutes the carbon is blown out.

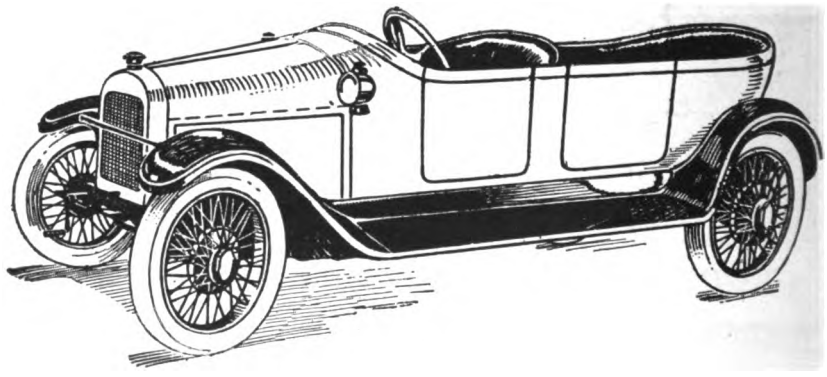
DEALERS!!! — A NEW ARRIVAL



THE LOWEST PRICED CAR IN THE WORLD

NEW
TWOMBLY

Built to Sell for $395, But Now Offered at the Exceptionally Low Price of

$195.

ABSOLUTELY GUARANTEED

WITHOUT AN EQUAL AT THREE TIMES THE PRICE—THE TWOMBLY IS THE MOST SENSATIONAL CAR VALUE YET ADVERTISED. IT WILL TRAVEL 40 MILES ON 1 GALLON OF GAS—200 MILES ON 1 QUART OF OIL AND WILL STAND THE ROUGHEST USAGE ON CITY OR COUNTRY ROADS.

The Twombly is a 2-passenger roadster. Go over the specifications and you will see that this is a car that you can sell without an effort.

Specifications—High grade 15 H.P., 4 cylinder, water-cooled motor; cantilever springs; 100-inch wheel base, high grade radial and thrust self-aligning ball bearings; underslung, giving low center of gravity and perfect balance; extra heavy clincher non-skid tires; high tension magneto, hand or foot control; weight 1025 lbs.

Equipment includes side and tail lights, and complete tool kit.

Our dealer proposition is just as attractive as the Twombly Car and its selling price. Don't delay, but write at once for details.

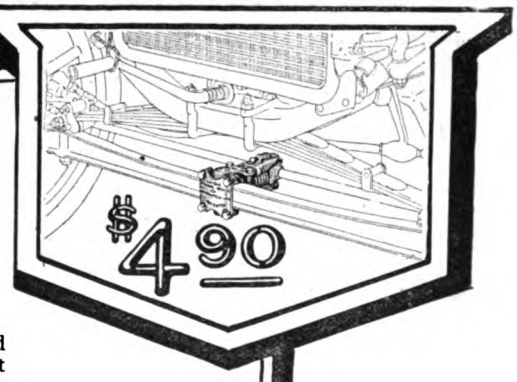
In every important city and in thousands of small towns and villages, in every state, over the entire country, you will notice

CONOVER COWL-WINDSHIELDS ON FORD CARS

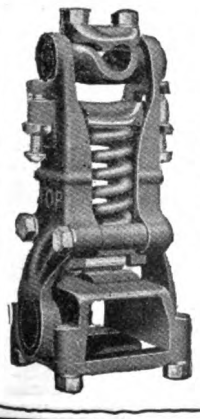


They make such a marked improvement in the appearance of Ford cars that you cannot help but notice them. They are self-advertising. Right in plain sight. Other accessories for Fords that are out of sight when in position on the car do not possess this important advantage. You have to keep pushing them ALL THE TIME. Progressive dealers realize this self-advertising feature of our shields and carry them in stock. We invite all dealers to avail themselves of this opportunity. Every Ford owner appreciates the desirability of a rain vision, ventilating windshield. We are TELLING EVERY FORD OWNER about our shields and are sending them to the dealers. So, Mr. Dealer, you want to be prepared to supply them, with a stock on hand. Better order 10 at least, at once. Some dealers order a car load at a time. We carry a large stock for immediate shipment. We are also selling, in large numbers, our UNIVERSAL shields for the new cowl-dash 1915 Fords. They are also rain vision, ventilating. They cool Fords perfectly in hot weather. They sell on sight. Conover cowl-shields, $15.00. Universals, $10.00.

STOCK UP AND BE PREPARED

PAGE WOVEN WIRE FENCE CO., **Adrian, Mich.**

Windshield Department



Dealers—Here is a Steering Device that is right both in theory and practice

A large number of steering devices recently placed on the market have failed utterly to do what was claimed for them. Why? Because they were not built on the right mechanical principle. You, no doubt, have tested one or a number of them and have found them inefficient. Don't judge the Savidge by these failures. Prove for yourself that the

Savidge Steering Device

Built Especially for Ford Owners

Will absolutely give you the perfect, positive steering control, easy steering, safe and comfortable driving that no other device can give. Because the Savidge embodies the varible-cam-principle that is vital and necessary to secure a perfect steering device.

No other device can be constructed on this principle because we own and control the basic patents.

The largest distributers in the U. S. are pushing the Savidge because they have been convinced by competitive test that it is the only real steering device made.

Hundreds of dealers tell of the splendid success they are having with the Savidge. One dealer says, "The Savidge is the most successful piece of equipment, of any kind, for Ford cars that I have ever handled."

Not sold through mail order houses. Write for our liberal selling plan.

The Bailey Gearless Differential

Big Profits for Live Dealers With Little Extra Effort

The Bailey Gearless Differential—not a new and untried device, but one that has been thoroughly proven by thousands of enthusiastic Ford owners—sells almost on sight to every one who drives a Ford car.

It is not so much an accessory as a necessity—for it eliminates at once most of the discomforts and dangers of driving.

On the straightaway it has all the advantages of a solid axle. There is entire freedom from the annoying and at times dangerous sidesway. The tendency to skid is practically eliminated.

On uneven roads, or in turning, power is delivered only to the wheel having traction. There is no waste, and no wearing away of the tires through the spinning of the wheels.

With the Bailey Gearless Differential the driver can pull through roads impassable with a differential-geared car.

It is guaranteed for the life of the car.

Prominent engineers tell us that in two years the differential gear on motor-cars will be a thing of the past.

Money-Back, No-Risk Proposition—Active Co-operation With Dealers

Our experience tells us that one Bailey Gearless Differential properly introduced in a locality means from fifty to a hundred more.

So we have made our introductory proposition exceptionally liberal. We do not ask the dealer to assume any risk. More than that we have devised a plan of co-operation with the dealer in his own territory that brings the prospect, already half sold, into his salesroom.

Write us today—for this really means big money.

Prices: 1 Gallon, $1.50; 5 Gallon can, $6.25. Sales proposition upon request.

THE NONCARBENE COMPANY, 1765 BROADWAY, NEW YORK

SPITLER PUNCTURE PLUGS

The Spitler Puncture Plug repairs punctures in automobile inner tubes quickly and without the use of cement, assuring a safe, permanent and economical repair.

The operation is so simple that a lady can make the repair without soiling her hands.

The plug can easily be taken out and used over again. A permanent repair in one minute.

To insert The Spitler Puncture Plug into the puncture, wet the tube before inserting plug.

Place the base of plug on edge and by stretching the tube at point of puncture, the plug slides in like a button in your coat. Then place cap over discs and screw lock cap firmly.

The Spitler Puncture Plug positively cannot cut the tube nor injure the fabric of the shoe for the principle is the same as the air valve on the tube.

Write for Circular.

Price—Four to a Set, $1.00.

(Patented May 11th, 1915.)

SPITLER PUNCTURE PLUG CO., Inc., United States Rubber Building, 1790 Broadway, NEW YORK CITY

The HUNTER

At Last, Mr. FORD OWNER! A SELF-STARTER For $10

Increases the Value of a Ford Three Times

NOTE THE ADVANTAGES

Powerful—The straight pull and powerful leverage enables a woman or girl to start it.

Simple—Installed in one hour. Nothing to get out of order.

Inexpensive—Costs little. No operating or installation expense.

Convenient—Easier to start motor from seat than from the crank.

Reliable—Entirely mechanical—can't fail to turn motor. Special attachment to close air intake of carburetor for easy starting in winter weather.

Appearance—Handle on dash all that shows. Crank not removed from front.

Every Ford Owner **wants to make his car up-to-date and at the same time provide for comfort.**

FORD OWNERS:—Write today for full description, or order through your dealer or direct from us.

DEALERS:—Don't fail to get our proposition at once. Big money for you in this—the lowest priced reliable Ford Starter made.

HUNTER LOCKS FOR FORD CARS:—A simple bracket and lock attached to steering column, making it impossible to steer car when locked. **Price, $1.00. Quickly installed. Sold by leading dealers.**

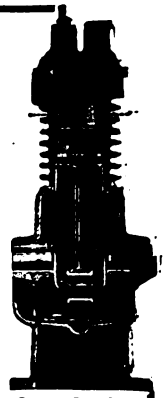
AIR FREE FROM OIL—

THAT IS WHAT YOU MUST FURNISH TO YOUR PATRONS IF YOU WISH TO GIVE THEM GOOD SERVICE.



CURTIS GARAGE AIR COMPRESSORS

will furnish AIR FREE FROM OIL because unlike all other air compressors the amount of oil furnished the cylinder is controlled—only sufficient oil furnished to properly lubricate without excess to be carried over into the air line. Examine the cross-section illustrated and note that neither crank nor connecting rod dip into the oil and the oil is not thrown direct into the cylinder.

Write Us For Full Particulars Of Either Stationary or Portable Outfit.

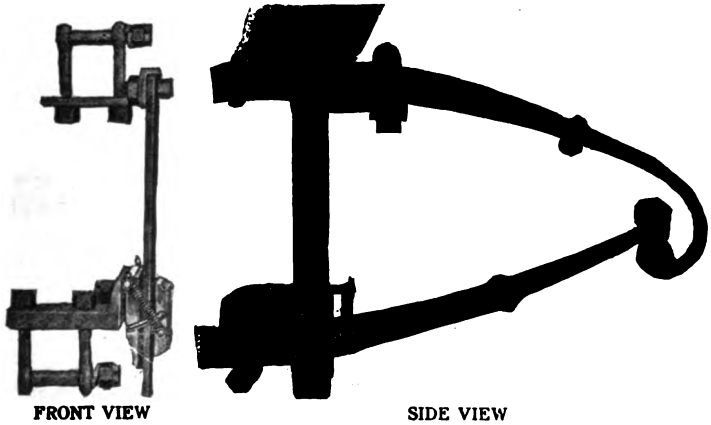
WHY REPAIRMEN SHOULD USE Marko STORAGE BATTERIES

It is an easy matter to convince Automobile owners that it is economy to use the best battery that money can buy.

Probably their previous experience with unreliable batteries will enable you to prove to their satisfaction that the "Marko" is the one they should use.



Now is the time when you should go after business.

Spring overhauling is at hand and batteries for starting and lighting purposes are an important item.

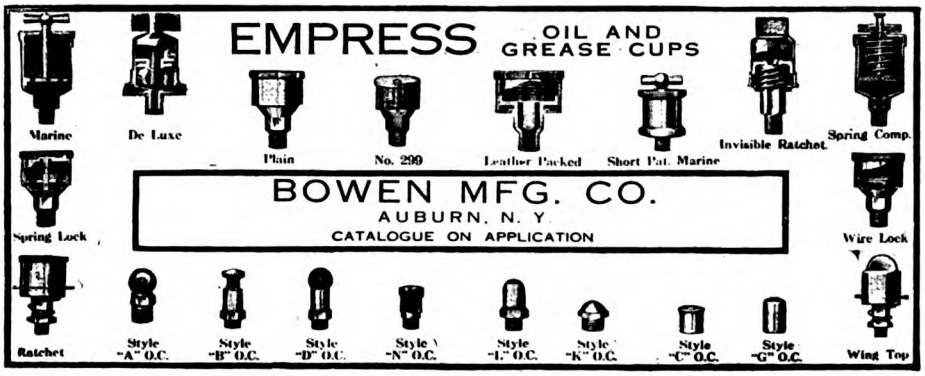
"Marko" batteries lead because of their great efficiency and reliability.

Write At Once for Our Proposition to Repairmen and Dealers.

PAUL M. MARKO & CO., 1191 Bedford Ave., BROOKLYN, N.Y.

FRONT VIEW SIDE VIEW

THE car springs with the shock absorber attached are like a compound bow and arrow of great power. When the springs rebound there is a brake on the arrow or rod of the shock absorber, resulting in an easy upward movement. The shock absorber will outlast the car.



Simpler, more reliable than any other, requires no care. Money back guarantee. They are cheaper than car repairs, wear and tear, besides the ease of riding.

THE KING DRAG

The Great Road Builder

In every part of this great country the King Drag can be used to advantage on country roads for putting them into proper shape at a moderate expense. We have brought out a pamphlet which gives full particulars of the use of the King Drag and how to make it.

In localities where the sentiment for good roads needs to be worked up, the distribution of these little pamphlets could not fail to do a good deal of good.

We will send a sample free of charge to anyone desiring to see it, and will supply the booklet at a dollar a hundred.

SELL the only BUMPER that can be struck without being damaged!

PATENTED

There are Bumpers galore—but only one that really protects and which won't break. The others are all alike. Their claims are strong—but their action mightily inefficient. The

=LYON=
Resilient Bumper

is different. You can run it into a pole at reasonable speed without injuring either the bumper or car! Strong statement? Prove it yourself at our expense.

The LYON is resilient, having ten times as much spring play as any other make.

The LYON is clamped on any car in 15 minutes; harmonizes with streamline bodies and is guaranteed not to rattle or become loose. It is packed in individual boxes, making it easy to reship. The price is low.

$7.50 up to $10.50; all finishes. FORD Bumpers $6.00

Why sell others that cost as much or more and don't deliver the goods? Give your customers their money's worth by selling them the LYON. We have something interesting to say to dealers and garagemen. ***Write us at once.***

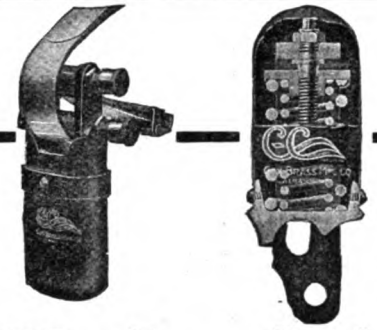
The best tire pump that money can buy. Can be installed by anyone. Will fill the largest tire in less than three minutes.



A Few Features of the Manzel Two-Cylinder Tire Pump

Has two cylinders, the most efficient design for a tire pump;—Runs smoothly and easily and gives a practically continuous flow of air;—Built like an engine;—All metal;—Fins for air cooling;—Has safety valve, cannot blow up the tires;—Supplies only pure air;—Only one place to oil;—Accurately made;—All parts fitted and ground;—Great efficiency;—Each pump tested to 250 lbs.;—Steel gears;—No machine work to attach to car;—Anyone can install it.

Dealers—If you are looking for a pump that will give satisfaction to your customers and a good profit to yourselves, write for our interesting proposition.

MANZEL BROTHERS COMPANY
321-323 Babcock Street BUFFALO, NEW YORK

Special Manzel Pump for Ford Cars only $7.50

2 Reasons
Why Every Dealer Should Sell C. C. Shock Absorbers

1. Because C. C.'s are made for both Heavy Cars and Fords, and you can sell every automobile owner in your territory.
2. Because the price is reasonable—***only $10.00 for set of 2 for heavy cars—$4.50 set of two for Fords, $8.00 for set of four.***

MORE REASONS

Because the price permits ***every*** car-owner to own C. C.'s.
Because you make ***quick*** sales—***often*** and get a good profit on each sale.
Because they are made to give long-wear, service and satisfaction—every set sold under the ***COX*** guarantee—now being nationally advertised.
Some dealer in your territory is going to take advantage of out National advertising and Dealer Helps and will make good money selling C. C.'s.
Why not you? Send for our free booklet, "Proof of Profit." It tells our story from ***your*** side of the fence.

Puts Pep In Motors

You men who sell or repair automobiles, get wise to the wonderful three-piece piston ring that puts PEP in gasoline motors. Ever-Tight is its name, and **ever tight** it is—always. New motors equipped with this ring give better service, and worn motors repaired with it are practically as good as new.

EVER-TIGHT

Piston Ring—"For Leaky Cylinders"

is composed of three perfectly grooved sections that play upon each other easily. It is so flexible that it instantly takes the form of an out-of-round cylinder, prevents power-waste, lessens friction and keeps oil out of the combustion chamber. This means full motor power and no carbon.

Ever-Tight is the only satisfactory three-piece ring made. Repairmen should write if local dealers do not carry it. We want jobbers and dealers in every city and town. *Write for particulars.*

DO YOU WANT A MOTOR CLOCK

For your car, and a good one? The clock illustrated in this connection is manufactured by one of the most reliable clock companies in the country and is warranted in every respect. It is not liable to get out of order. It has interchangeable parts. It is the product of skilled labor combined with the most improved Waltham Automatic Machines. This clock is 3⅜ inches high, and has a Porcelain dial 2½ inches in diameter. It has a one day movement with second hand. It can be furnished in burnished brass or nickel plated whichever is preferred. The arrangement we have made enables us to furnish **one of these clocks and a subscription to the Automobile Dealer and Repairer for a year** to all residents of the United States and its territories for the precise price the clock retails for, namely, **$2.50.** If an eight day clock is preferred send 50 cents extra or $3.00. Canadian subscribers should add 50 cents extra to cover the extra postage required on the **Automobile Dealer and Repairer.** This clock cannot be sent to foreign countries. The clock can safely be sent by mail and will be forwarded postage prepaid to any part of the country. Remittances can be made in any convenient way. Address

MOTOR VEHICLE PUBLISHING CO.
71-73 Murray Street, - - - - New York, N. Y.

Every Repair Shop or Garage
SHOULD HAVE A CLOCK.

We have recently made very favorable arrangements with one of the largest clock companies in this country by which we are enabled to offer to our readers in the United States or its territories a **Regulator Eight Day Calendar Clock** 38½ inches high, with a 12 inch dial, finished in **Oak** or **hand-rubbed Mahogany**, with a subscription to the **Automobile Dealer and Repairer** for one year, at the very low rate of **$3.90.** This clock cannot be sent to any foreign country except Canada, and Canadian subscribers must send **50 cents** more to cover extra postage on the paper.

Every repair shop, garage or dealer's office should have one of these clocks. It will give you the time of day correctly and the day of the month.

The engraving shown gives the correct appearance of this clock.

This offer is good for either old or new subscribers.

Remittances can be made in any convenient way. **Be sure to state** whether you want this clock in Oak or Hand-Rubbed Mahogany.

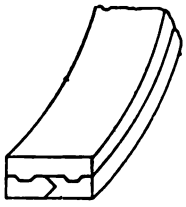
IF

one piece piston rings could exert the same pressure against the cylinder walls at every point,—

and if

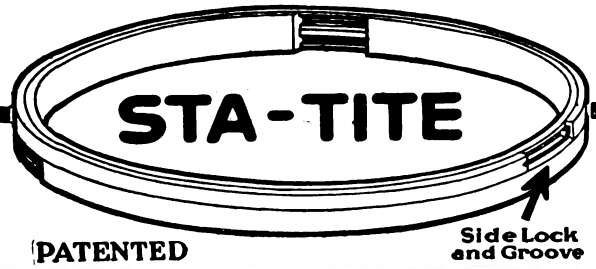


two piece piston rings, under stress, did not work "egg shaped" and "out of round"—

then three piece piston rings would not be a necessity.

But three piece piston rings are absolutely necessary to stop that costly leakage of power and compression.

"A Motor Is No Better Than Its Piston Rings."
Efficiency Ed.



Sta-Tite Piston Rings are made up of three individual interlocking rings grooved together with their section openings so distributed that multiple contact against the cylinder walls is always assured.

LEAKAGE IS A MECHANICAL IMPOSSIBILITY

Special Inducements to Dealers and Agents. Rings in all sizes. Write for literature.

CITRUS
CUBA

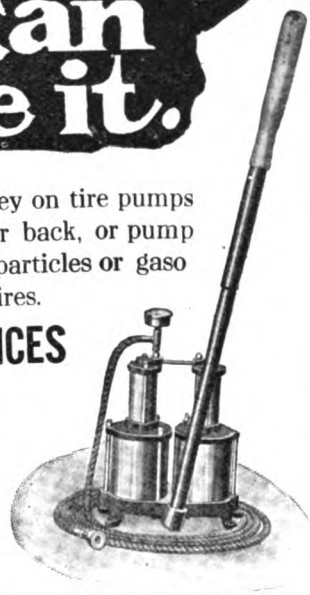
Wonderfully rich land, good water, good title. Outdoor life the year 'round. A ten acre grape fruit grove will pay you $2,500 per annum for life. Eastern Cuba is to be the great winter playground of the American. The land is so fertile and accessible that fortunes are to be made in fruits and vegetables. Great country to relieve and cure rheumatism, nervous and respiratory diseases.

Present price of land $50 per acre. No frost and no irrigation or fertilization required. The young man's opportunity and the old man's paradise.

The grape fruit raised here surpasses in flavor and quality anything grown in Florida or Southern California.

The most delightful place in the world for a winter home, and very accessible. Boats sail from New York to all the principal ports, and at very reasonable rates.

For literature and further details address the



CITRUS DEVELOPMENT CO.
101 Tremont St., Boston, Mass.

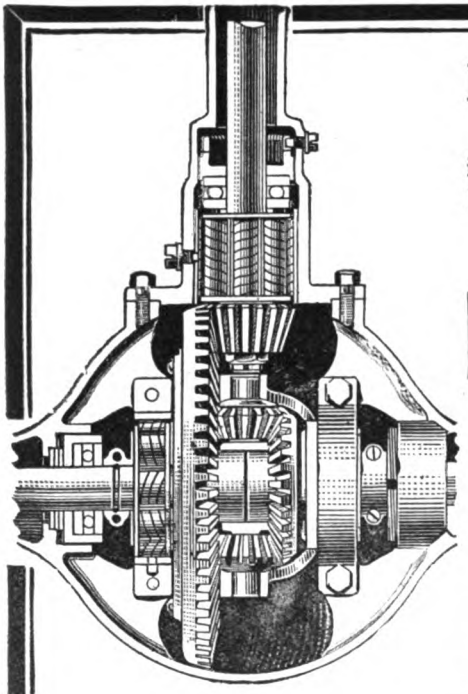
At Our Risk—You Can Prove it.

Don't waste good money on tire pumps that either break your back, or pump **Rubber Rotting** oil particles or gaso line fumes into your tires.

TAKE NO CHANCES

At our risk you can prove that the **"Dead Easy"** is quicker, safer, easier and cheaper than any other tire pump, either engine drive or hand power.

"DEAD EASY"



Convenient to carry with any car, it is always ready for instant service. The gauge showing exact tire pressure, there is no guesswork—and it's "Dead Easy."

Differential Lubrication IS VITAL

Its bevel gears and ball and roller bearings **must be unfailingly lubricated.** Its mechanism is a hot-bed of friction when lubrication fails. **Insure proper lubrication, by using**

TRADE MARK REGISTERED IN

NON-FLUID OIL

UNITED STATES PATENT OFFICE

NON-FLUID OIL is **especially adapted** to this exacting requirement. **It never fails** to envelop the gears and bearings with a heavy coat of durable lubricant,—not merely wet them like **oil** or film them like **grease.** The gears **never fail** to mesh in a soft, yielding cushion—metal never touches metal—the only wear is a slow, oily polish which transmits power with least friction and with least loss.

"K No. 000"
for differential, compression cups, and all bearings.
"K No. 00 Special"
for sliding gear transmission

GET A CAN TODAY AND PROVE IT

Reduced prices for 1915. *Ask your dealer. The* ***original*** *NON-FLUID OIL is identified by the orange-colored can bearing the above sprocket-wheel trade mark. Avoid substitutes.*

MOTOR EYE

DETECTS MOTOR TROUBLE INSTANTLY

Flashes a warning of danger before the harm has been done. The motor is the car's most costly piece of mechanism and should be given protection commensurate with its importance. A ruined motor means a ruined car. $2.50 invested in prevention may save $100 expended in repair bills.

A radiator thermometer is the only known means for instantly detecting trouble beneath the hood of a running car.

READY TO ATTACH

$2.50

MOTOR-EYE is the cheapest motor insurance obtainable. Don't pay more for devices that won't do more.

Pin a money order to the attached coupon and get one of these little sentries out on your radiator cap keeping a never-tiring eye on what is going on inside. Money refunded if not satisfied.

STA-TITE

There's Good Profit for Dealers Who Sell

STA-TITE PISTON RINGS

"Power to Burn—Without Waste"

They so increase the speed and power of a motor and are so economical that every user is delighted and soon sends his friends into your store for some of these wonderful STA-TITE Rings.

Made in three sections—two outer rings fitting over an inner ring—they effectually prevent loss of compression, and by keeping oil from the combustion chamber, stop waste, excessive formation of carbon and smoking.

STA-TITE Rings fit perfectly, last indefinitely, and are fully guaranteed. They sell fast because they are the best rings to be had, increase power and save money.

We also make "Quality" snap rings— cast individually—the best ordinary piston rings to be had. All sizes carried in stock.

Get our dealers' price—it means good profit for you.

A
NEW IDEA
A New Invention
DYKE'S
AUTOMOBILE
and
Gasoline Engine
INSTRUCTOR
By A. L. DYKE.
Originator of the first Auto Supplies, Publisher of the first practical book on Automobiles in America.
You learn the PRINCIPLE and CONSTRUCTION of ALL parts of ALL automobiles.

Prepared for the novice, but a handy reference for the expert.

Dyke's Automobile and Gasoline Instructor
Complete **$8.50** (add 60c. to prepay)

It teaches the principle of Automobile, Motorcycle, Marine, Stationary and Aero Engines.

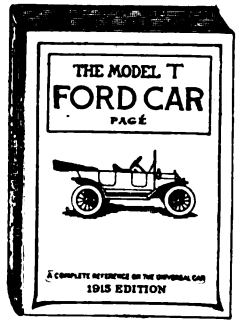
HOW TO REPAIR, ADJUST AND DIAGNOSE TROUBLES
Also covers Salesmanship

Every subject is treated, such as **ENGINES**, with all the different valve arrangements, etc. **CARBURETION**—beginning at the simplest form, to the adjustment of all leading makes. **IGNITION**—from low tension coils to high tension magneto systems. **Care of a Car**; Operating a Car; Lubrication, Building and Equipping a Garage, for home or pleasure; Self-Starters—in fact, every subject is fully covered.

VALUE OF THIS INSTRUCTOR TO YOU

WE CLAIM that with careful study of this instructor, it will enable you to become. 1) **AN ENGINE EXPERT** capable of diagnosing ignition, carburetion, valve timing, cooling troubles, and remedying them. (2) **A DIAGNOSIST** who from knowing the principle and construction of all subjects, can instantly tell the cause of any trouble and apply the remedy. (3) **A RUNNING GEAR EXPERT** capable of diagnosing and remedying such troubles as differential, transmission, axles, brakes, steering wheels and axle troubles (4) **AN AUTO MECHANICIAN** who can adjust and remedy all the troubles after diagnosing. The subject of repairing in this Instructor is complete in every respect.

Price of ENCYCLOPEDIA, 600 pages, 1000 illustrations, $3.25 postage prepaid.



FREE—96 page Supplement with 175 illustrations on Electric Starters, Generators, Six, Eight and Twelve Cylinder Engines—with purchase of Auto Instructor.

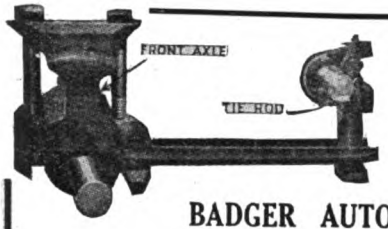
Vulcanizers—Air Bags That Stand Hard Use

Long Life in Goodyear

If you have troubles with sectional air bags in repairing tire casings, end them now. The Goodyear Air Bag is made to give you the service you have long demanded. The Goodyear Sectional Air Bags are made of durable fabric and will not "burn up." They last with ordinary treatment for 50 cures. They are easy to handle, too. They have a rawhide loop in the end for removing bag from casing. This prevents breaking off the valve stem, a common occurrence with ordinary air bags.



It is these little perfections of detail that have given to Goodyear Repair Materials their present prestige among dealers. You should know more of these Goodyear Tire Accessories—22 Tire Savers. There is a big profit to you in selling accessories that stay sold because of satisfaction rendered.

Write for our complete list, with your prices and profits. Address Desk 154

Don't Scrape Motor Bearings By Hand—REAM Them

The bearings of a motor can be reamed out in one-quarter the time required for hand scraping, and a better job done if you use a

MARTELL A-L-I-G-N-I-N-G REAMER

By the hand scraping method it is impossible to secure perfect gear mesh and accurate alignment, and the surfaces of the bearings are not perfect. By the new method of ***reaming*** it is easy to secure accurate gear mesh, absolute alignment, perfect bearing surfaces, and an exact size of bearings to fit the crank shaft. The aligning shaft is adjusted in position in the bearings by means of eccentric bushings which may be delicately manipulated until the gears mesh perfectly and the bearings are in line.

Send for free booklet describing the reamer and its method of use.

"Bridgeport" Pumps

Built to Give Service, Not Just to Be Sold

Every feature in the construction of "Bridgeport" Pumps is the result of development work—the aim of which has been to improve their service and lasting qualities.

There are no flashy features of doubtful value to attract the unwary or to substantiate a price.

"Bridgeport" BRASS CO. TRADE MARK

"Bridgeport" Pumps are the best made pumps on the market today. They are made with seamless brass tube barrels which cannot rust. The cylinders are "lapped" into the footbase in the strongest joint possible to be made. The wide-grip handle makes it easy to give a powerful stroke without pinching your fingers. These are but a few of the many good features of **"Bridgeport"** Pumps.

They're the kind of tire pumps you can depend upon.

At Last! What All Ford Owners Have Long Waited For

THE NEW YORK AUTOMATIC HEAD LIGHT CONTROLLER FOR FORD CARS

PRICE $5.00 Patents Pending

A LIGHT EQUALLY AS POWERFUL AS $50.00 BATTERY SYSTEMS

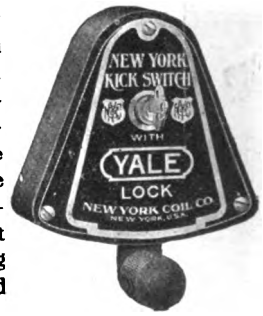
Delivers a powerful light at the lowest engine speed. Uses the Regular Ford magneto, requiring no batteries or complications. **Entirely automatic in its operation**—no belts, gears or movable connections to the engine are employed. **It also prevents the bulbs from becoming burned out at excessive engine speed.** This is positively the first and only solution to the electric head light problem on Ford cars. We furnish necessary wires already connected so that anyone can install in ten minutes by the simple removal and replacing of one bolt.

You need one—Why delay? Send us $5.00 with the understanding that you may return the device if you desire.

INSTALL A GENUINE

New York Master Vibrator on Your Ford Car

Price $8.00 at Your Dealer's
and enjoy the smooth, evenly applied power so noticeable in six-cylinder engines . . .



It is immaterial if your car is the latest or oldest model. You need our master vibrator, as it dispenses with all coil adjustments and replacements, and insures easy starting, a hot, perfectly timed spark under all conditions, and entire freedom from ignition troubles. It has for the past six years proven itself to be superior to any existing type. Though many times imitated it has never been equalled and stands today the best in its class at any price.

With fittings to install on the new 1915 models.

Prevent your Ford from being stolen by buying

OUR NEW YORK KICK SWITCH WITH YALE LOCK---PRICE $2.50

which fits the new Ford metal or wood coil boxes. This is a handsomely constructed **kick switch containing a genuine** Yale **Lock,** which affords the convenience of the regular Kick Switch, but possesses the locking feature which is found in no other type.

Anyone can install—Remit $2.50 today—Money back if not satisfactory

Two Ignition Systems for Ford Cars

The New York UNI-Coil Ignition System for Ford Cars

PRICE $15.00

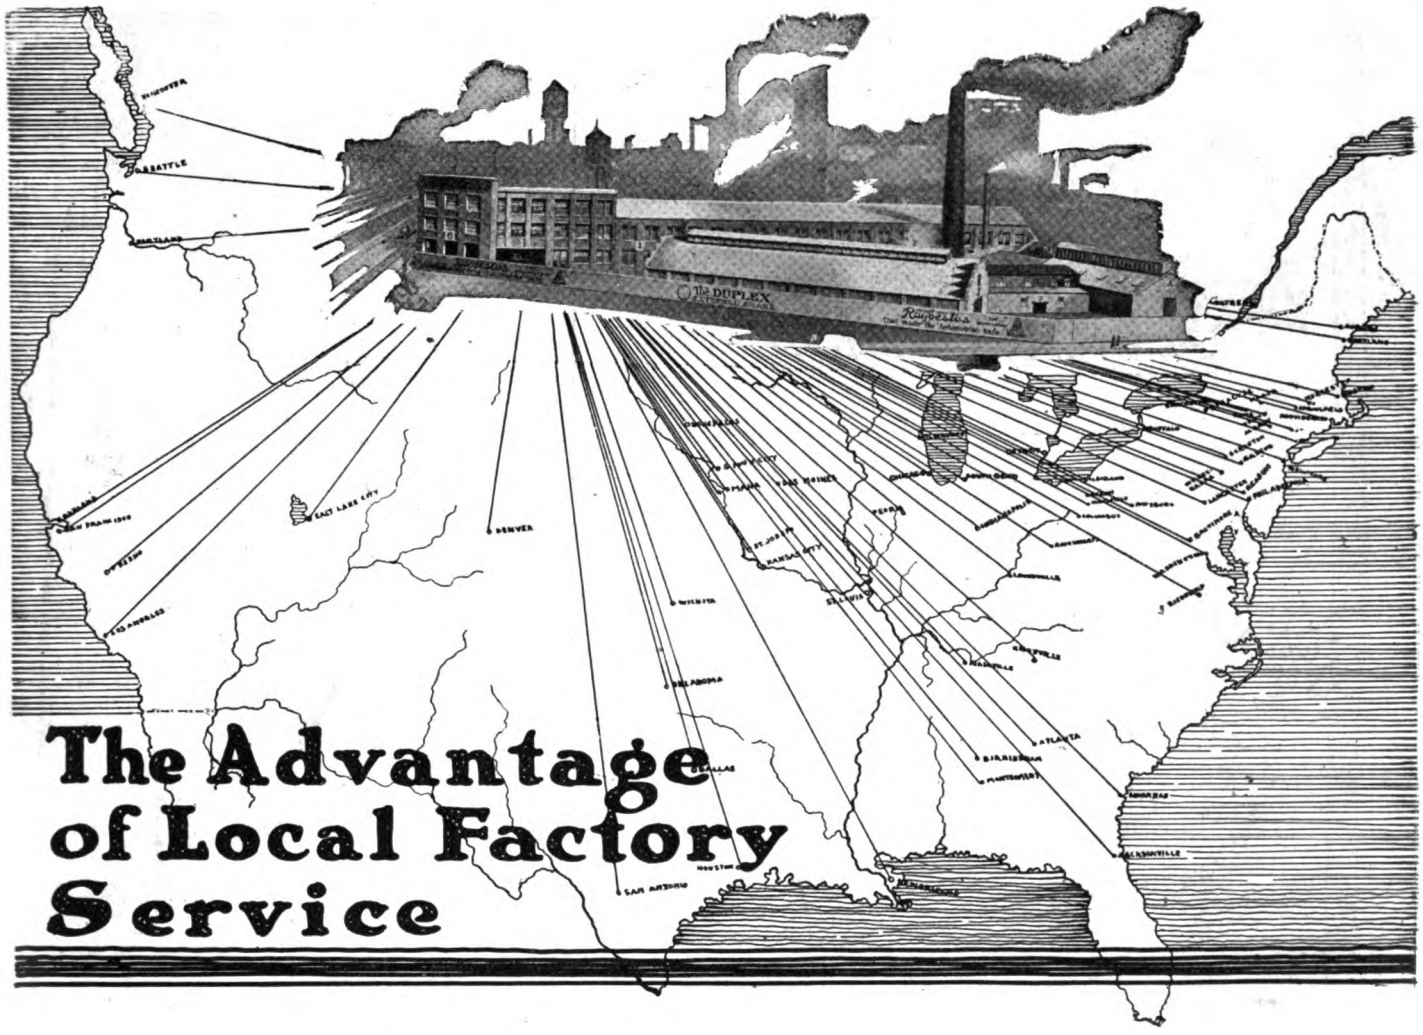
Operated by the Ford Fly Wheel Magneto (or Battery)

This system is primarily intended to operate on the Ford fly wheel magneto. It consists of a well-made elevating gear bracket upon which our Combined Timer and high tension Distributor is mounted. The Distributor is of the most simple construction containing the essentials of the high tension magneto. It uses one unit equipped with vibrator of your regular Ford coil. It dispenses with the timer and practically all of your present wiring, insuring a perfect timed spark and freedom from trouble.

The only satisfactory distributor system for the Ford magneto. Furnished complete to the smallest detail.

The Rhoades Battery Ignition System

is intended for the class of Ford owners who prefer to ***dispense entirely with vibrators.*** This system operates entirely on battery, six dry cells supply ignition for from two to four thousand miles. ***We supply a handsome non-vibrating coil fitted with kick switch,*** also elevating gear bracket. Six years of hard service have proven it to be the best battery system obtainable for Ford cars.



PRICE $20.00

The Advantage of Local Factory Service

NO MATTER where your business is located our system of distribution offers you every advantage our factory in Bridgeport can give Bridgeport dealers, garage and repair men

There are upwards of one hundred distributing organizations in the United States who carry on hand at all times a complete stock of RAYBESTOS—all sizes—a stock adequate to supply any demand, short of the requirements of a big automobile manufacturer.

TRADE MARK Raybestos REG. U.S. PAT. OFF.

The RAYBESTOS Distributor in your city or in the city nearest your town can, and will, quote you the same prices, terms and discounts as the home office and serve you to better advantage than the home office because of the saving in time and expense involved in receiving, billing and shipping your orders—large or small.

Each RAYBESTOS Distributor is, so far as business relations with you are concerned, a direct factory branch.

It will be to your benefit to take advantage of our local factory service.

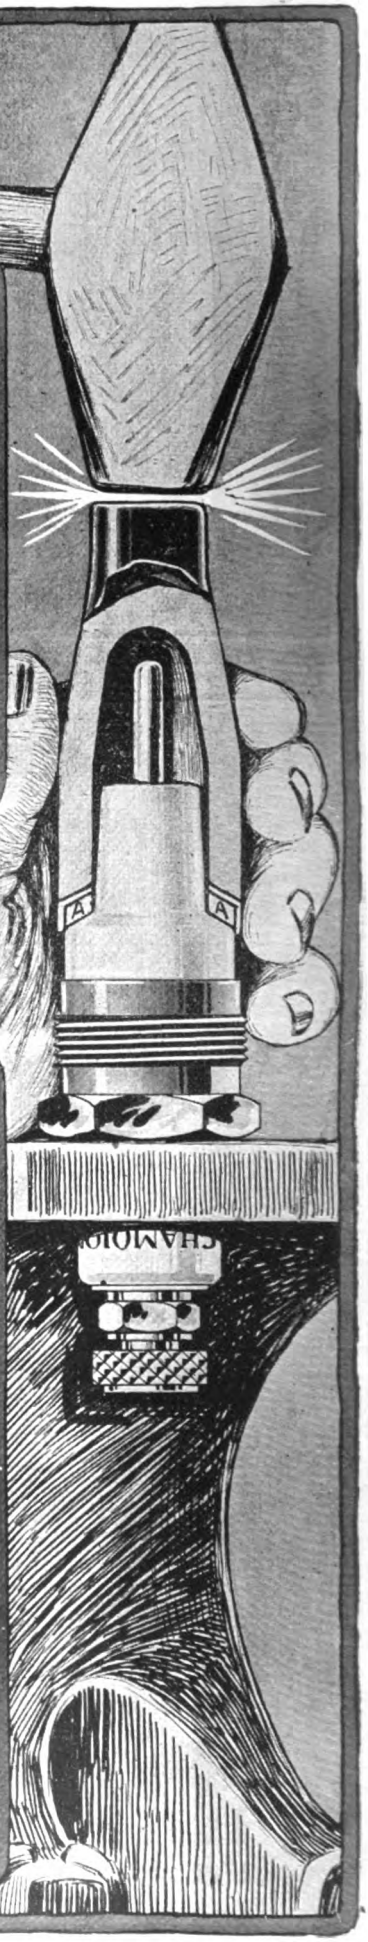
Champion "O" Special ½-inch, Price $1.00
Special equipment for Overland cars

Champion Conical ⅞-18 Long, Price $1.00
Specially designed for Buick motors



Champion One-Piece Heavy Stone, all sizes $1.25
For high powered automobiles, trucks, and stationary engines

How We Protect the Porcelain

Champions have an asbestos cushioned copper gasket (A in illustration) at the exact point where the porcelain insulator must take the terrific force of the hammer-like explosions in the cylinders.

This is why Champion Spark Plugs endure these heavy trip-hammer blows without breaking or even cracking.

It is one of the fundamental exclusive features back of Champion Reliability.

Champion

"TOLEDO MADE FOR THE WHOLE WORLD'S TRADE"

75% of all American-made gasoline motors for every purpose are equipped at the factory with Champion Spark Plugs.

This fact, in itself, is responsible for a heavy Champion demand. Experienced motorists seldom fail to be guided by the expert opinion expressed by automobile engineers in this manner.

Our extensive national advertising campaign is continually increasing the market for Champions. Are you taking advantage of this?

Follow the example of most of the successful dealers. Make your spark plug line exclusively Champion.

Our Profit Sharing Agreement

Dealers who did not secure our profit-sharing contract for all of 1915 should not fail to get one effective for the last six months of the year. See your jobber's salesman or write direct to us.

Champion Spark Plug Company

2006 Upton Ave. Toledo, Ohio

Don't Throw Away Your Half-Worn Tires

They're Still Good for 5,000 Miles

European Methods of Half-Soling Tires Makes Them Run 10,000 to 15,000 Miles. Signed Guarantee for 5,000 Miles Without Puncture. Skidding Rendered Impossible.

You Take No Risk—We Ship On Approval

The man who throws away his half-worn tires or sells them to the junk man for a few cents a pound is just as extravagant as the man who throws away his shoes when the first sole gets thin.

For over three years European motorists have been "half-soling" their tires, just as we half-sole our shoes. As a result, they are getting 10,000 to 15,000 miles out of ordinary pneumatic tires, while American motorists are getting from 3,000 to 5,000 miles—and what is just as important, they have almost entirely eliminated punctures, blow-outs and rim cuts with their ever constant dread. To say nothing of making skidding impossible.

Save $50 to $200 a Year

Figure this out by the individual—how it affects you—your pocketbook.

Every mile you travel on the bare tire is costing you from 1½c. to 4c. in tire wear alone, to say nothing of the lost time and expense for the repair of punctures and blow-outs.

Just stop for a moment and consider what it means to you to get 10,000, 12,000 or 15,000 miles out of your tires and at the same time drive your car without the constant nerve-racking dread of tire trouble and skidding.

In round numbers it means a saving of $50 to $200 each year—a saving sufficient to pay your gas and oil bills each month. Yet this saving is not all—the tire vacation and relief from skidding assured you certainly means a gratification which cannot be estimated in dollars and cents.

No More Skidding

Durable Treads are as sure footed as a Rocky Mountain burro, and they're supremely convenient.

They are studded with sharp-edged steel rivets which dig right down through the mud and slush and get to earth every time. In London and Berlin, as well as many other of the larger cities of Europe, ordinances compel the use of the steel studded Treads for public safety.

Durable Treads are always on your tires—you don't need to worry about climbing out in the rain and mud to adjust your chains, and—what is more important, you receive perfect non-skid service while your tires are protected instead of injured. They cover the tire completely, extending entirely around from rim to rim. Nothing can work its way in between. They afford a perfect protection—that's why we can guarantee them as we do.

No Matter How Cut or Worn They Are

No matter how cut or worn they are, you can get more mileage from them and the few cents the junk man would give you can be turned into dollars.

The strongest proof of the economy of Durable Treads is their unprecedented record of sales: 40% of the business comes direct from recommendations of users; in eight months the sale of Durable Treads increased over 700% in the United States alone.

Where is there an automobile accessory which has received such instant and country-wide endorsement?

Think of it—a 5,000 mile tire vacation—to be able to FORGET tires!

This is a pretty strong statement unsupported, but it's not merely a claim.

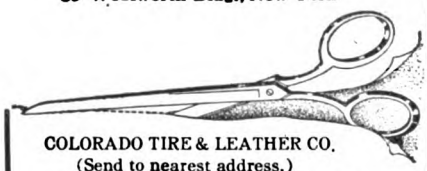
Durable Treads are delivered to you under a signed guarantee for 5,000 miles of wear without puncture.

This guarantee is an ironclad agreement—as good as a government bond and holds good whether your tires are new or old, tread worn, rut worn or rim cut.

Special Discount Offer

To motorists in territory where Durable Treads are not as yet represented we offer a special introductory discount for advertising purposes, equal to the full dealer's profit.

We have made some strong statements in this advertisement. Make us prove them. You have everything to gain and absolutely nothing to lose, for all we ask is the opportunity to give you a demonstration at our own expense and risk.



We have a catalog, sample and copy of written guarantee ready to send and they're yours free for the asking.

Don't let the tires on your car run another week in "bare-footed" condition—don't wait until you get your next puncture or blow-out.

Fill out and mail the coupon right now and you will hear from us within a week; no expense and no obligation to you.

Announcing

Campbell Detachable Upholstery

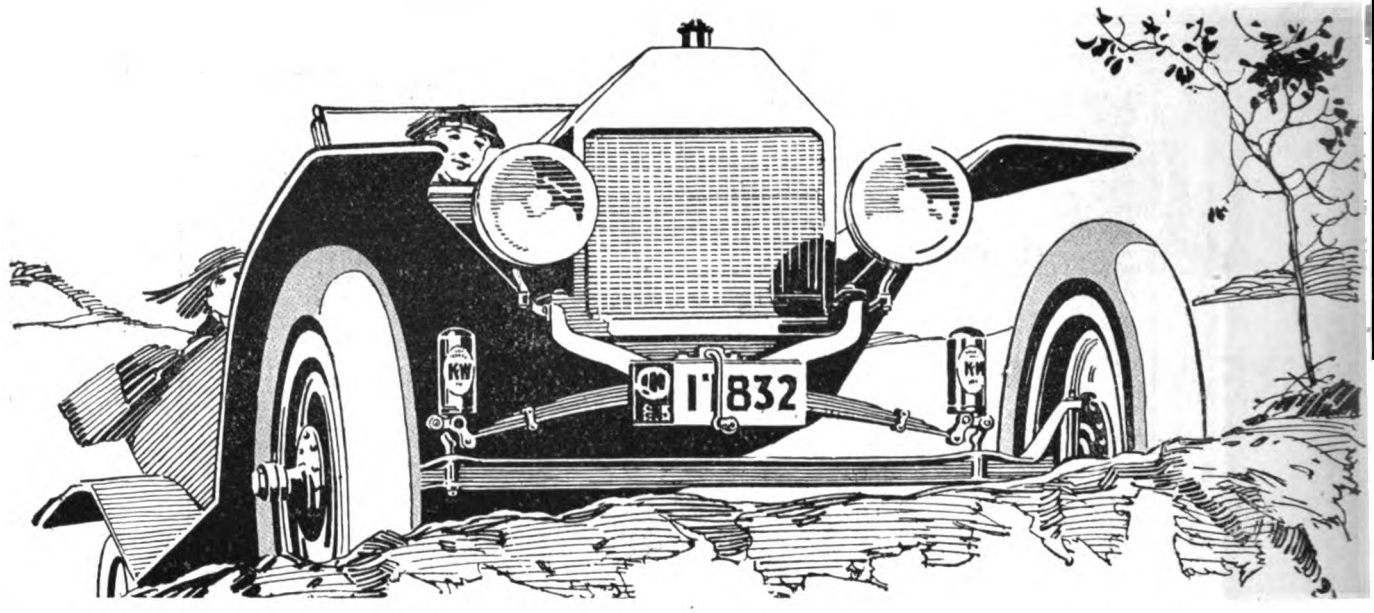
(The First of a Series of Full Page Advertisements in the Saturday Evening Post, Literary Digest, etc.)

WHAT a Paris frock does for a woman, Campbell Detachable Upholstery does for a motor car—*classes* it.

Over the shabby upholstery of last year's car, or the shining newness of this year's, it works a genuine transformation. At a stroke, it gives the interior trim a luxurious look, a soft warmth and *tone*, found only in the finest limousines.

There is a set specially designed for practically every model of every car. It fits over the regular upholstery like the upholstery itself, becoming in appearance an inherent part of the car body. Anyone can install it—no alterations are necessary. With a snap of its fasteners you adjust each hand-tailored part over seats, backs, arms and doors. With equal ease you slip it off for cleaning.

There is the same satisfaction in owning a car equipped with Campbell Detachable Upholstery that there is in being faultlessly dressed. There is an added comfort, and a very practical satisfaction in the always cool, always clean seats. If you are buying a new car, ask to see it equipped in this latest style. If you want to make an old car look like new again, order its particular set of Campbell Detachable Upholstery from your dealer—today.



Dealers: Write for folder of fabric samples and discounts.

Campbell Detachable Upholstery is made in a variety of smart motor fabrics and linens, to harmonize with cars of every color. Send for folder showing actual samples, and price list, with special discounts to the trade. Address The Perkins-Campbell Company, 628 Broadway, Cincinnati, Ohio. New York Office, 89 Chambers Street.

CAMPBELL

The name Campbell on the fasteners is the quality mark of genuine Campbell Detachable Upholstery.

Digitized by Google

Enjoy the Scenery—Forget the Bumps

Be a Tourist—Not a mere Road Inspector

Many motorists today are slaves to the road. Their daily drives and week end trips are limited because of rough, rutty roads. They arrive home tired from being bumped around and "picking the roads"—they see nothing else all day.

Don't be a mere road inspector—equip your light, economical Ford with K-W Road Smoothers and get the greatest enjoyment and comfort.

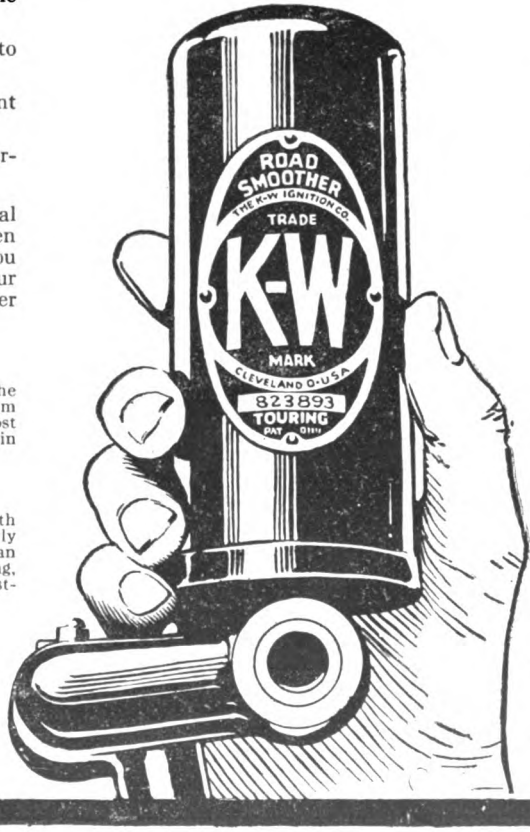
K-W Road Smoothers give you this enviable comfort because their design combines these four factors:

1. A spring to effectively take up the shock.
2. An anti-rebound air chamber to check the rebound.
3. Anti-side motion links to prevent side rocking and swaying.
4. A construction that does not interfere with the steering.

Each of these features is in itself vital to your comfort and safety. It's only when they are combined in one device that you will get the greatest pleasure from your car. Here's how the K-W Road Smoother fills all these requirements:

The K-W Spring

A helical spring that effectively takes up the shock, made of electric smelted, chrome vanadium steel. The K-W bracket design allows almost *twice the length of spring action* or "travel" (in actual service) of any other.



The K-W Air Chamber

The anti-rebound air chamber with its smooth fitting piston acts like a door check, and gently "eases off" the rebound of the spring. This is an exclusive K-W feature. Its design provides a strong, tough, self-lubricating piston, working in a dust-proof air chamber. It requires no attention.

The K-W Side Motion Links

Made of the highest grade heat-treated drop forgings of remarkable toughness. This enables them to withstand the great strain put upon them. They prevent your car from pitching, swaying or skidding while making sharp turns.

$15 SET OF FOUR ONE FOR EACH WHEEL

K-W Bushings

All bearings are phosphor bronze throughout. That means long life.

But you can find all these vital factors *only* in K-W Road Smoothers

That is why they lengthen the life of your car, by eliminating shock and vibration. Tire economy is assured, because K-W Road Smoothers enable the wheels (not the whole body of the car) to follow the contour of the road. That means no grinding off the rubber of the tires. K-W Road Smoothers always make good because they are built with characteristic K-W Quality throughout.

But after all's been said and done, it's results that count; and the K-W guarantee covers not only workmanship and material, but *results* as well.

K-W Road Smoothers are quickly and easily attached. No holes to drill and no tools necessary except a wrench. And the final and biggest advantage you get from K-W Road Smoothers is that they increase the radius of your car's usefulness, and bring you home with that "satisfied feeling" after a day of comfortable motoring.

If your dealer can't supply you, sent prepaid upon receipt of price.

Write for booklet "That Satisfied Feeling"

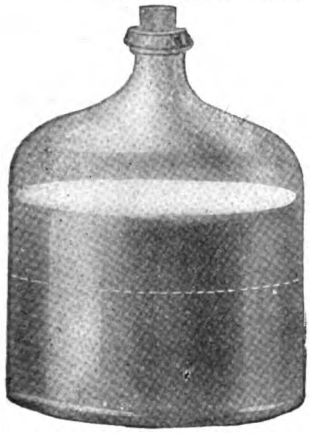
STANDARD **Hartford** EQUIPMENT FOR **Ford** CARS

REAL BIG-CAR COMFORT FOR FORDS

Controlled spring action at the front, greater resiliency at the rear. Result—real big-car comfort.

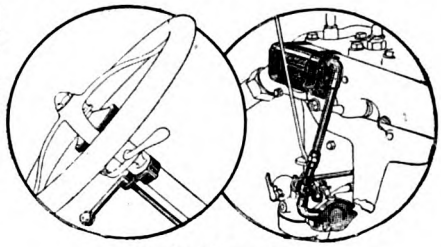
The Hartford Comfort Combination makes every road a boulevard for Ford owners. At front, where the greater weight is, the Hartford Shock Absorber prevents violent movement of the front springs; at rear, where less weight is, two Hartford Cushion Springs supply the needed resiliency.



Hartford Comfort Combination

Try this combination. It's a comfort-maker.

*Hartford SHOCK ABSORBER On the front of a Ford AND Hartford CUSHION SPRING On the rear of a Ford



PRICE {ONE HARTFORD SHOCK ABSORBER / TWO HARTFORD CUSHION SPRINGS} **$12.00**

That Above Dotted Line Shows the Saving

Is a Saving of 35% in Gasoline a Consideration?

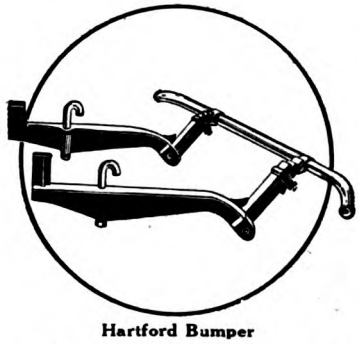
If so, get acquainted with a Ford accessory that cuts down your "gas" bills over one-third, gives greater power to your engine, makes it run more smoothly. The

Hartford Economizer

Hartford ECONOMIZER

feeds more air and less gas to a Ford engine, furnishing an ideal mixture. It's a genuine **economizer** and its price is exceedingly low—

$6.00, COMPLETE



Lengthens the Lines of a Ford

enhancing its good looks while protecting lamps, radiator, mudguards **and car.** That's why a

Hartford BUMPER

is the best bumper for a Ford. It is shock-absorbing. When something hits its bump bar, the force of the collision is dissipated by friction leaves of spring-steel. **All** your Ford is saved from harm. Bolts on without drilling.

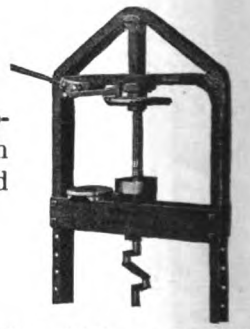
Do ALL of Your Repair Work and do it at a Profit with a

WEAVER
GARAGE PRESS



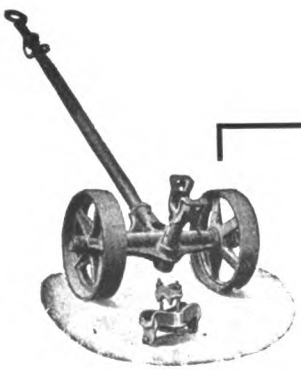
Stop paying out money to some "machine" shop for handling your difficult jobs—

A **Weaver Garage Press** will eliminate that outlay and bring jobs from other shops to **you.**

Don't antagonize and exasperate your customers by tying up their cars for two or three weeks while you send work "to the factory" which you **should** handle in your own shop—

Install a **Weaver Press** and **surprise** them by repairing their cars "while they wait"—They'll come back and bring others.

For Automobile Work



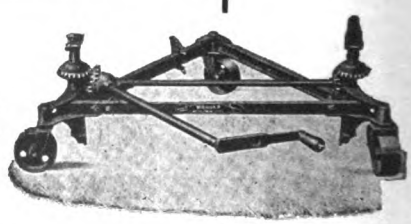
This Press was designed to handle the problems of the Auto Repairman. It is wide enough to accept an auto wheel and can be adjusted to meet practically any requirement.

Built Right

Leverage 1500 to 1; from 74 inches high, made of one piece of heavy 5-inch Channel Steel; ball bearing wheel with Bronze thrust bearings. **The Screw does not revolve.** Width between frame 32 inches; perpendicular adjustment 48 inches; weight 425 lbs.

Net Price (Complete with Equipment) $48.00

WEAVER Auto Ambulance

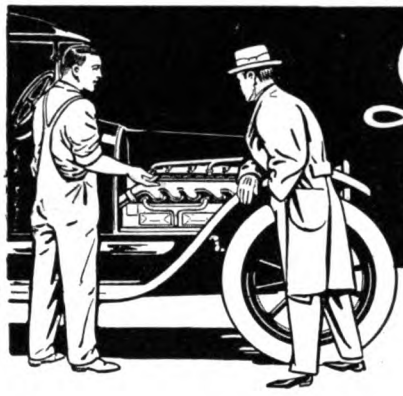


For towing disabled cars; will attach to either front or rear axle. Roller bearing *Cast Steel* Wheels; telescoping tongue.

Weight 140 Lbs.
List Price.....$30.00

WEAVER Auto Twin Jacks

One man can handle any car with ease. Full ball and roller bearing casters and lifting mechanism. Made in **two** sizes.



Per Set (Two)
$20.00 —— and —— $36.00

Dealers - Attention

Money for you when times are dull

Lots of your customers think they can't run their cars in winter. They're right enough, too, if they've known what starting trouble means and had experience with power failure on the road—been stalled a few times in the snow or mud.

They put their cars away and your business with them comes to a standstill until they begin to get ready for spring.

We're out now with a plan to get automobile owners sold on the idea of running their cars through the winter months. We're going to show them that winter weather need have no terrors for them if they take out power insurance with a set of

Made in All Sizes **LEAK-PROOF** *Easily Adjusted*

Piston Rings

MADE BY McQUAY-NORRIS MFG. CO.

Page advertisements are coming out this month in the leading automobile journals reaching car owners, and we've accumulated enough experience to know that arguments like those we're putting up are going to "get over." No owner wants to store his car if he can be shown a way to keep it in use.

Your chance to make dull times busy times, is to get behind us and push LEAK-PROOF PISTON RINGS with your customers. Talk LEAK-PROOF to them. You know what these rings can and will do to make winter driving easy and economical. Dealers everywhere have made good profits in this business—and good friends out of their trade besides.

Don't be put off the track with imitations or substitutes for LEAK-PROOF PISTON RINGS. This is the only piston ring so designed and constructed as to make leak proof service always sure and efficient. Note the angle-to-angle interlocking construction of the two members and always use this feature to identify the LEAK-PROOF Ring.

Write for Free Booklet, "To Have and To Hold Power"

It explains Leak-Proof construction—gives you facts and arguments that will sell your customers on Leak-Proof Rings.

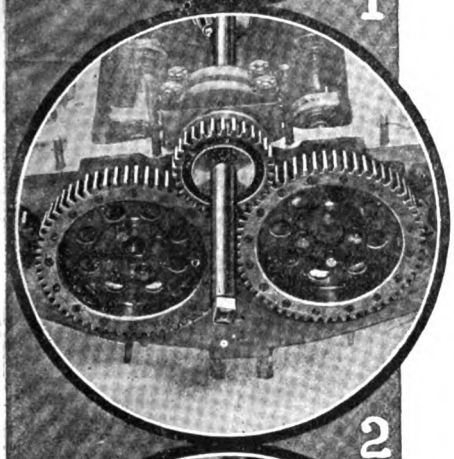
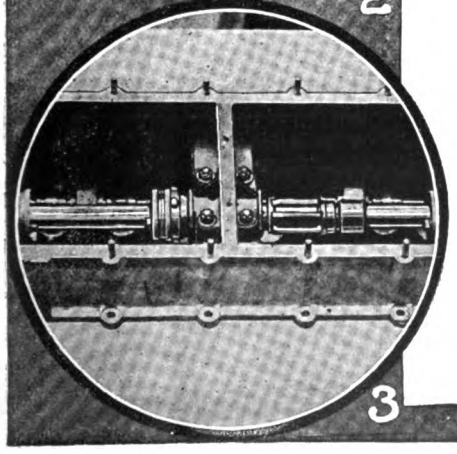
For Motor-Bearing Work



Bearings can be bored out in absolute alignment and to the exact size of the crank shaft with the

MARTELL A-L-I-G-N-I-N-G REAMER



It takes but one-quarter the time required for hand scraping.

1

2

3

Better Bearings in Less Time

To scrape in a set of motor bearings by hand is a long, hard job requiring from three to five days. The work is seldom satisfactory—it is so difficult to meet the requirements of perfect gear mesh, absolute alignment, and accurate size.

This work of scraping motor bearings can now be done in an exact, scientific way in one-quarter the time required for the hand process. This is done by means of the MARTELL ALIGNING REAMER.

This tool will bore out the bearings to exact size, leave them in perfect alignment, permit the proper mesh of gears, and will burnish the bearing surfaces. The reamer equipment consists of the aligning shaft, two reamer heads, six adjustable bushings, and a short shaft for connecting-rod bearings.

The reamer head may be set to exact size by micrometer (See Fig. 1), after calipering the crank shaft. By means of a special bushing the crank shaft gear is located on the aligning shaft so that it will run in perfect mesh. (See Fig. 2.) The aligning shaft is supported by eccentric bushings, secured in a tapered sleeve having fine threads on the tapered portions. These are screwed securely into the ends of the bearings to be reamed. (See Fig. 3—which shows middle bearing.) The eccentric bushings are provided with flanges, on the faces of which are vernier scales reading in .001 of an inch and recording the *amount* and *direction* in which the reamer shaft is moved.

Carry Your Spare Tire on the Extra Rim Furnished with Each Set of PARKER-HYDRAULIC PRESSED STEEL WHEELS FOR FORDS

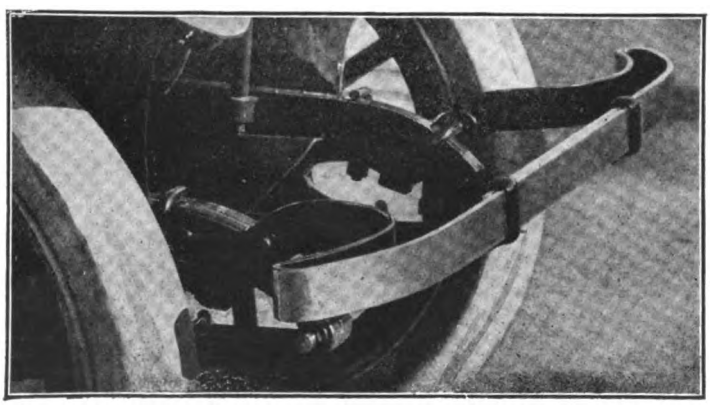
They give you the quickest and easiest demountable rims—the only part to come off being the rim itself. No loose parts—nothing to stick—rims cannot be mounted crooked—and always run true.

To change a tire simply unscrew each bolt about two turns. This loosens the clip and releases the rim.

These wheels are the strongest wheels made, yet they are much lighter than wooden wheels with demountable rims. This great strength insures your safety, which alone is worth many times their first cost. Their handsome non-rustable and durable finish adds to the attractiveness of your car.

Sold by reliable dealers everywhere. If you don't know yours, write us.

These wheels offer a real opportunity to live dealers. Full details on request.



$19.75
SET OF FOUR

Enameled black, 30 x 3½ inch wheels, spare clincher rim, full set of new hub bolts and brace wrench. With wheels enameled red and clincher rims enameled black, $20.50.

SELL the only BUMPER that can be struck without being damaged!

PATENTED

There are Bumpers galore—but only one that really protects and which won't break. The others are all alike. Their claims are strong—but their action mightily inefficient. The

LYON Resilient Bumper

is different. You can run it into a pole at reasonable speed without injuring either the bumper or car! Strong statement? Prove it yourself at our expense.

The LYON is resilient, having ten times as much spring play as any other make.

The LYON is clamped on any car in 15 minutes; harmonizes with streamline bodies and is guaranteed not to rattle or become loose. It is packed in individual boxes, making it easy to reship. The price is low.

$7.50 up to $10.50; all finishes. FORD Bumpers $6.00

Why sell others that cost as much or more and don't deliver the goods? Give your customers their money's worth by selling them the LYON. We have something interesting to say to dealers and garagemen. ***Write us at once.***

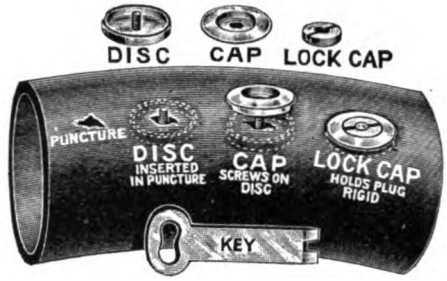
SPITLER PUNCTURE PLUGS

The Spitler Puncture Plug repairs punctures in automobile inner tubes quickly and without the use of cement, assuring a safe, permanent and economical repair.



The operation is so simple that a lady can make the repair without soiling her hands.

The plug can easily be taken out and used over again. A permanent repair in one minute.

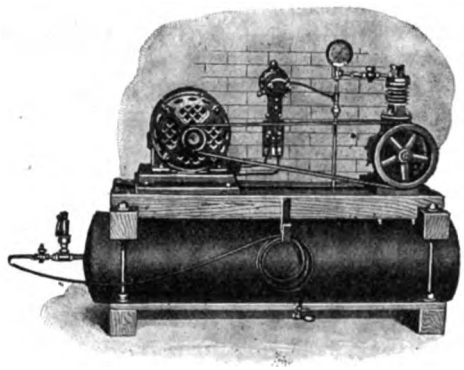
To insert The Spitler Puncture Plug into the puncture, wet the tube before inserting plug.

Place the base of plug on edge and by stretching the tube at point of puncture, the plug slides in like a button in your coat. Then place cap over discs and screw lock cap firmly.

The Spitler Puncture Plug positively cannot cut the tube nor injure the fabric of the shoe for the principle is the same as the air valve on the tube.

Write for Circular.

Price—Four to a Set, $1.00.



(Patented May 11th, 1915.)

MUSKEGON - MICHIGAN

The Foundation of this Tire

is just as good as the day it was bought. Any tire with good fabric, whether there is any rubber on the outside or not, is suitable for the

TRIPLE TREAD PROCESS

The Triple Tread is the only tire protector made

that does not depend on inflation, rim pressure or mechanical means to hold it in place, so that the style of bead on your tires cannot affect the success of their treatment.

In Vulcanizing the Triple Tread on your Tire

we are able to fill the pores of the leather with rubber, making it waterproof, so that by bringing the leather down the sides and over the bead of the case, covering it completely, we are able to keep dirt and water from getting under the tread to rot the fabric, and also to strengthen the sides and bead of the tire.

Write for our booklet,
"Worn Out Tires Made New."
Please mention the size of your tires.

To Avoid Trouble on the Road Take Mileage With You

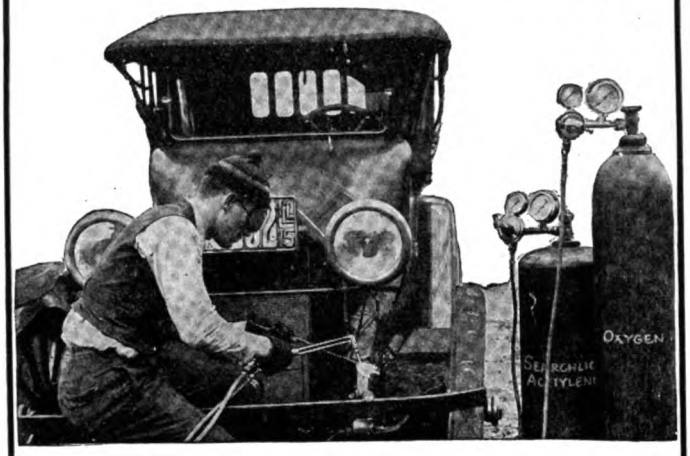
The Miller process of building tires prevents trouble by avoiding its cause — by retaining all the natural vegetable wax and oil in the cotton fabric. This keeps it from becoming brittle and weakened and gives it the power to resist. For a blow-out comes from the inside — from a bruised and deadened fabric. The Miller process of building

Miller Geared to the Road Tires

does not cook this life-giving lubricant out of the fabric or destroy the native toughness of the rubber, but retains both and makes a rugged unit of them. No Miller tire is handicapped in its manufacture—therefore not handicapped on the road.

The price of a tire is meaningless until it has been proven on the roads. This is why Miller users stick to Miller Tires. The roads have proven every Miller claim to be the whole truth—and the Miller price to be actual economy.

The answer to the skid question is Miller **Geared-to-the road** Tires! Scientifically built, they gear your car to the road through mud, sand or slush. **With Miller tires on your car you're in control. Its tread is an integral part of the tire and retains its safety features until the entire tire is worn out.** The greater mileage you get from them will make your choice of Miller Tires an economy, as well as a permanent safeguard.



MILLER TUBES answer the tube question.

Ask the Miller Dealer to show you a section of the Miller Tire

Here Is Where The Big Profits Lie

The work your competitor can't handle, is the work which makes you your biggest money. . . .

You'll find no end of profitable work like this for a *Searchlight Welder.*

You will be able to repair broken castings and auto parts easily, quickly and cheaply, getting a long price because of the strength and neatness of the job and because of the time saved for the delayed tourist.

You will also be able to build up a very profitable general repair business with the factories in your neighborhood.

Broken castings which tie up factory machinery often cost hundreds of dollars in profits lost. No process or method of repair (or even of replacement) can compete with the Acetylene Welder. It is easily portable. You can carry it right to the job. You make repairs without even dismantling the machine. Guarantee a good, quick job, and quote a good fat price. You will get it every time.

The *Searchlight Welder*

For Garages

Is the only welder in its class which sells for less than $100. **Our price** for complete equipment is only **$50.00** (cylinders of gas extra, of course).

Write for complete information and we will show you the new source of big profit.

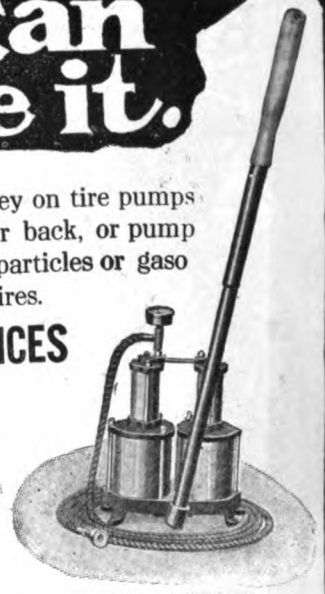
These men are making from $1,500 to $3,000 a year clear profit. You can do it too—with an Akron-Williams outfit.



The A-W Repair Outfit is used and endorsed by 30 leading Tire Manufacturers. So you take no chance in equipping with Akron-Williams. We'll help you to learn the business. Write for our catalog No. 121 and learn the great money-making possibilities of Tire Repairing and how little money you need to start.

THE WILLIAMS FOUNDRY & MACHINE CO.
Glendale Ave., Akron, Ohio

At Our Risk—You Can Prove it.

Don't waste good money on tire pumps that either break your back, or pump **Rubber Rotting** oil particles or gaso line fumes into your tires.

"DEAD EASY"

TAKE NO CHANCES

At our risk you can prove that the **"Dead Easy"** is quicker, safer, easier and cheaper than any other tire pump, either engine drive or hand power.

Convenient to carry with any car, it is always ready for instant service. The gauge showing exact tire pressure, there is no guesswork—and it's "Dead Easy."

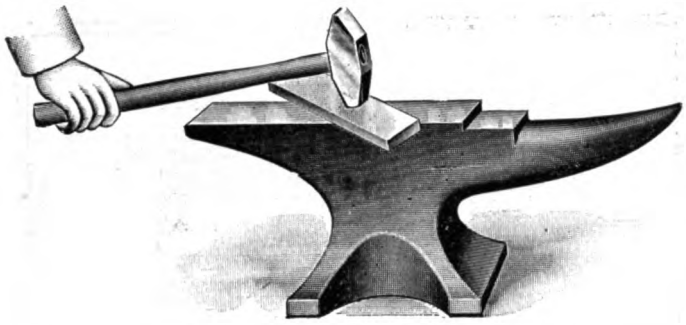
INLAND 1 PIECE PISTON RING

A perfect one-piece Piston Ring

that has all the virtues of eccentric, concentric and more-than-one-piece construction; and none of their disadvantages.

A continuous ring cut spirally for half its circumference; heat-treated so that the free ends hug tightly together; the result is an absolutely *gas-tight* ring that uncoils in expanding, insuring uniform pressure and perfect contact with the cylinder walls.



The strongest gas-tight ring on the market, because of its simple one-piece construction, and, for the same reason, it costs less to buy, and less to install, for it is easier to put on and will not break in handling.

Absolutely guaranteed; money refunded on any ring that fails to give perfect satisfaction after 90 days' trial.

Full description in free booklet.
Dealers and jobbers should write for interesting prices.

F. E. WELLS & SON CO., GREENFIELD, MASS., U. S. A.

Going!

After 400 miles, the tire is cut by a sharp stone or a piece of glass.

Going!

After 800 miles, the hole is still further enlarged and dirt has been forced under the tread forming a "sand-pocket"

Gone!!

After 1200 miles the inner tube has blown clear through the casing—throw it into the junk-heap.

The small cut or little hole exposes the fabric to sand and water—causing sand pockets, and rotting the fabric. The outside coating of rubber on an automobile tire is intended to protect the "carcass" or fabric of the tire from wear and water. Keep the protecting coating of rubber in good condition and you will greatly increase your mileage.

SHALER Vulcanizer

Trebles Your Mileage

You can repair any puncture, blow-out, tear or hole in a few minutes with a Shaler Vulcanizer and make the repair the strongest part of the tire.

Remember that your old tire might just as well have run 10,000 miles. The new one ***will*** run 10,000 miles if you vulcanize it with a Shaler.

Prevent Blow-outs and Save Repair Bills

by keeping your tires in sound condition. Every time you seal a cut or repair a hole in your casing you prevent a blow-out—and possibly a serious accident—that is bound to occur if the cut is left open and the fabric exposed to dirt and water. A little intelligent care of your tires will pay big returns in the saving of repair bills and increased mileage.

GET OUR FREE BOOK **"Care and Repair of Tires"**

Every motorist needs it, because it tells what to do for every kind of tire trouble and gives valuable hints about the care of tires. Catalogue gives full information about our complete line of vulcanizers—Electric—Gasoline—Alcohol and Steam for every requirement of the motorist's use at home and public garage service.

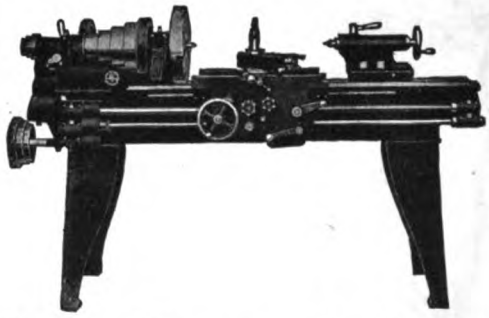
The Most Perfect Piston Rings Made

PERFECTION PISTON RINGS



They are made of soft, elastic steel in sections 1/16" wide and one section is required for each sixteenth in width of the groove. They give compression and power to your motor unequalled by any other rings. They present a barrier to the gas in the combustion chamber such as cannot be possible with a one piece ring.

This construction gives perfect compression, maximum power, minimum carbon, smaller oil consumption, lower gasoline bills, less smoke, and saving in repair bills. These rings are put on the pistons without being stretched, and this is impossible with one piece rings, which are always distorted when stretched over the pistons.

PERFECTION PISTON RINGS are made in all sizes and can be sold by dealers to great advantage. *Let us give you special quotations for your requirements.*

Install Micro Two-Part Pressure-Tight Rings

and you will save their cost in lessened regrinding of valves and decarbonizing of cylinders.

Without other benefits Micro Rings are highly profitable, but they also save much oil and gas, and assure a service improvement on leaky old type rings.

You would like the lastingly better compression, the snappy start and steady pull of a Micro-equipped motor, especially when climbing hills and traveling over bad roads.

Micro ring parts individually cast from fine grained flexible gray iron and machined to micrometer accuracy, are safe from breakage in placing and always fit close against the cylinder walls.

Write for our dealers' proposition and booklet, "How Micro Rings Improve Efficiency."

Add $250.00 A MONTH EXTRA To Your Business

REPAIR AUTOMOBILE TIRES

Sounds like a whole lot of money to clear extra every month. Seems almost impossible, but that is what hundreds of men are doing who have added a Tire Repair Department to their business. **The investment is small, the profit large** and **returns quick and all cash,** besides the demand for tire repairing and retreading is constantly growing. Your garage is by no means complete, your business is not as profitable as it can be until you get in on the Tire Repairing and Vulcanizing end.

THE HAYWOOD TIRE REPAIR EQUIPMENT

Answers all the requirements to successfully handle this end of the business. With it and a little business judgment, success is certain. Every year adds thousands of new auto owners. They are looking more and more to economical tire service. The day of discarded tires is over, the Haywood Equipment makes this possible.

HERE IS YOUR OPPORTUNITY

Either as a side line to your present automobile business or as a business by itself, the Haywood Equipment will make money for you. **Tires go wrong all the time.** You know that. Keep them in tune. Give your customers complete service—repair their tires and all. This builds business and makes you rich. Experience unnecessary. You can learn easy—or teach a boy to handle this end. Be the boss and make the money. Learn the details now. Investigate. Act quick. Be the first. Send name and address only. A postal will do.

"For Leaky Cylinders"

Coast to Coast With Ever-Tight Piston Rings

WHEN E. G. Baker established his coast to coast record of 11 days, 7 hours and 15 minutes, his Stutz Bearcat Motor was fitted with Ever-Tight Piston Rings.

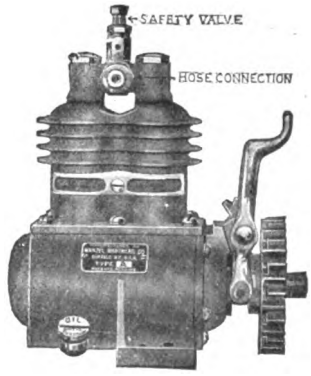
Read Baker's opinion *after* the trip:

Gentlemen:
With reference to my recent trip from San Diego to New York, I beg to advise that I owe much of my success to the Ever-Tight Piston Ring, inasmuch as the car did not lack a bit of power, and the way it pulled through the sand and took the hills and mountains was certainly remarkable. The EVER-TIGHT Piston Rings truly deserve full credit for their reliability. Yours very truly,

E. G. BAKER.

Confirm Baker's opinion yourself by trying Ever-Tight Piston Rings the first time your motor needs overhauling.

They work as well in out-of-round cylinders as in perfect ones. Their three-piece construction prevents leakage and gives wonderful flexibility. They hold compression with minimum friction and never bind.



Ask your repair man.

We want jobbers and dealers in every city. Write for full particulars.

The Tire You Have Been Looking For
The Woodworth Trouble-Proof Tire

A perfectly resilient pneumatic tire that is guaranteed against punctures and guaranteed to outwear any other make of tire on the market.

In the Woodworth Trouble-Proof Tire there is a puncture-proof leather strip which is perfectly soft and flexible so that the tire is not stiffened or any extra heat generated. This tire will ride and run as easy as any ordinary pneumatic tire.

Think of the satisfaction of having a tire that is guaranteed trouble-proof; of knowing when you start out you will reach your destination without tire troubles and that you obtain this not only without extra cost but at a cheaper cost per mile than with ordinary tires.

Send for free booklet giving full description and prices.

LEATHER TIRE GOODS COMPANY, Manufacturers, NIAGARA FALLS, N. Y.

EASYON TIRE CHAINS
The Handy Traction Chain

You do not intend to use Tire Chains unless it is absolutely necessary, but when you have to use them you want chains that you can put on easily. EASYON CHAINS can be applied or removed in a moment even when stuck in the mud.

EASYON CHAINS are packed with a set of eight in a bag, taking little room in the tool-bag and if you have them with you you can feel sure you can pull out of any place where the car has power enough to drive it.

Price $3.20 per set for tires up to and including 4 inches.
Price $4.00 per set for tires larger than 4 inches.

If your dealer does not have them we will ship, parcel post, on receipt of price.
Carry a set of EASYON CHAINS and get a grip on any roads.

RADIATOR REPAIR.

Full Directions as to the Necessary Tools and Methods for a Good Job.

From J. N. Bagley, Nebraska.—Ever since the beginning of automobile repair, the radiator has been to the repairman a sort of bugbear, and nearly every repairman dreaded to undertake it, but instead, would put into it a little compound of some sort, in the hope a temporary repair could be made until someone else would make a permanent one. Occasionally we find a repairman who has the nerve to tear into the radiator, and even rebuild it. To do the ordinary repair job, no great number of tools are needed. Occasionally a radiator freezes, or meets with an accident, which makes the repair a trifle difficult, but the ordinary leaks are not at all hard to handle, if taken in time.

The tools shown in Fig. 1 are all simple and inexpensive, and with them many jobs can be done, if care is taken. At A, we have a common pot for heating the irons. At B, we have an iron with a hook bill, which comes in good play for getting on the back side of a tube to repair a crack or a seam. At C, we have a common iron, with the point tapering, one corner sharp and one round. At D, we have a pair of long-nose pliers, which come handy for pulling the tubes and handling the fins. At E, we have a pair of ordinary pliers, with a couple of strips of steel, 1 inch by 1/8 of an inch. This tool comes in good play for straightening the kinks out of the fins. All that is necessary to remove a kink

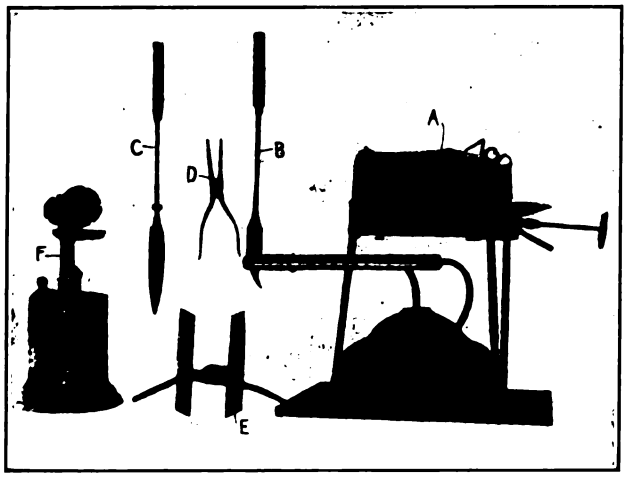

Fig. 1.

is to place the tool over the fin, grip it firm, slide it the length of the fin, and it will come out straight and true. This is not necessary, but it improves the looks of the job quite a little.

At F, we have the ordinary blow torch, which is a part of every garage equipment, and will be found useful in melting joints apart. In tearing the radiator apart, care should be taken that the parts are not pried while hot, as the brass of which they are made is very brittle when heated, and unless caution is used the crimped edge will be broken off, making it a trifle difficult to put it together to make a good-looking job. If it be necessary to remove some of the tubes, as in case of freezing, it will be advisable at first to remove both top and bottom. This is done by applying the torch flame to the parts sold-

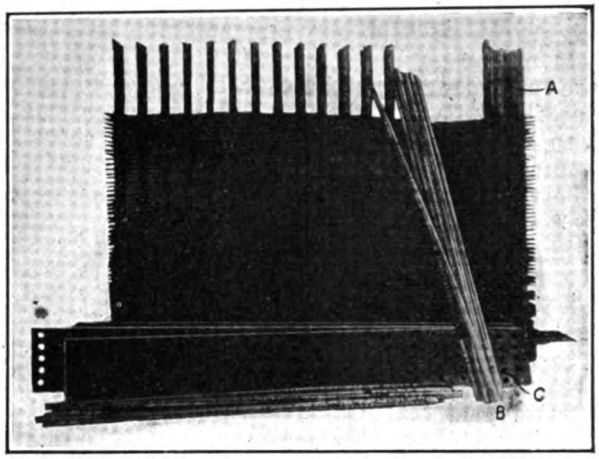

Fig. 2.

ered together, and, as fast as the solder is melted, it should be shaken out and the parts tapped apart sufficiently to prevent their being stuck together again. Continue to melt apart the joints of top and bottom, until the body of the radiator is all that is left containing the tube. In this condition, it is an easy matter to draw the defective tubes from the radiator.

To remove the tubes, take the snipe nose pliers, catch the projecting end, play the flames of the torch up and down the tube, until the solder in the fins is melted, and with a firm pull, the tube will slip out and leave the hole free and clean. Continue to pull the broken tubes until none remains.

To test the tubes for leaks, use a small rubber tube, with a nipple on the end. That will cover the end of the tube; a pump connection, such as the Acorn, will answer well. Stick a small plug into one end, and apply the water pressure to the other. If the tube leaks, it will be seen at once. No great amount of pressure is needed, as five or ten pounds will do the job very successfully. A very good plan is to have a small tank, holding about five gallons of water, under the pressure wanted, and a small valve between the hose and the tank, so that the pressure can be released at will.

Now that we have drawn all of the defective tubes, we are ready to supply the new ones. The new ones can be purchased, or they may be taken from old radiators that have been discarded; in fact, I prefer taking them from old radiators, as it saves buying, and the old radiators are of no value except for junk. And by tearing up the old radiators, one

Digitized by Google

can learn quite a little as to construction, which may some time be quite valuable in repairing. When pulling out tubes for repair use, we should be a trifle more careful than when we pull the broken and defective tubes. Play the torch up and down the tube until it can be slipped out. While it is still hot, and the clinging solder is in a melted condition, take a cloth and stroke it the entire length to remove the little lumps of solder that cling to it, as if allowed to remain in bunches, they will interfere with placing them again in the next job.

In Fig. 2, we have a radiator body, with the defective tubes removed and ready for the perfect tubes to be placed. The tubes shown have been taken from another radiator, which is quite a saving, when everything is considered. To replace the tubes, we will begin at the row of tubes in the next row, A, which have not been removed.

Now, with the torch flame, we will play up and down the fins, at the same time keeping it far enough away, so that the fins will not be burned. As soon as the particles of solder remaining on the fins are melted, take the long-nosed pliers, grasp the tube at the end, and slide it down in place, taking pains to keep all the ends even, or nearly so. Continue until the tubes have been replaced, when we shall be ready to replace the fins, which have been taken from another radiator. The fins are very thin, and will not stand abuse, so, as we come to replace them, we shall have to take one for a pattern, and make a template of iron, one-eighth of an inch thick, to force them to place at one operation, for, if we were to place one end down and the other up, we would stretch the fin and it would not look well.

After replacing all tubes and fins, it is necessary carefully to go over the testing operation again, to see that no tubes have been placed that have leaks

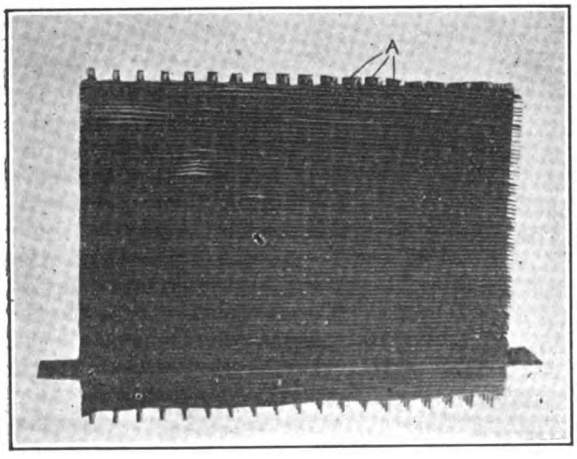

Fig. 3.

in them, or that none of them has been damaged in the operation of replacing them. Go carefully over the projecting ends, both top and bottom, and straighten up such edges as have been jammed or closed during the operation of making the changes. We are now ready to proceed with the assembling of the radiator, as all tubes are tested and placed, as well as fins, as shown in Fig. 3. Now that we have inserted all missing tubes, as shown at A, Fig. 3, we are ready to place the top on the radiator, which had been removed to allow of the tubes being replaced with new.

After setting the top back over the tubes, which has a sheet with a hole for each and every tube to stick or project through, we must, after placing it, go carefully over the end of each tube, and solder it to the plate, to prevent its leaking and running down the outside of the tube. All the ends of the tubes, as shown at A, are tinned, and will solder fast to the already tinned plate in the top with little trouble.

We have, in Fig. 3, a number of fins, which have been jammed, but these we will leave in this condition until the job has been completed, so far as repair is concerned, as in shifting it about they may become jammed and bent more or less.

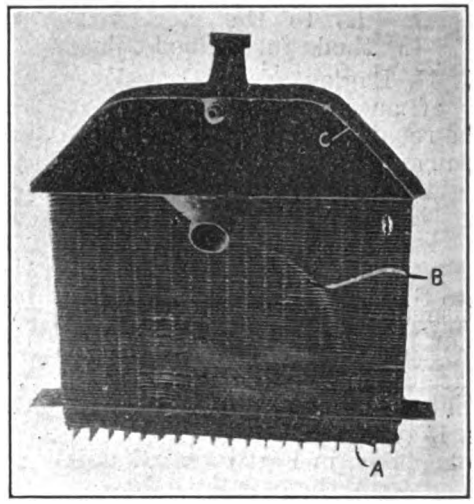

Fig. 4.

In Fig. 4, we have the top, back and seams, at C, soldered up. We also have, at B, on the back side of the radiator, some more of the jammed fins to straighten up, when the bottom is placed and the jacket is fastened in position. The seams, C, should be soldered carefully, and made as smooth as possible, as these joints are exposed, and around the front of the top no more solder should be used than is necessary to make the job tight.

Now that the top has been placed in position, the tubes projecting through the bottom should be straightened up, as in the top and bottom, placed in position, and the ends of all the tubes soldered to the plate. After all soldering is done and the bottom made secure, before placing the jacket, the radiator should be tested for leaks. This can be done by placing water in it, and using about 5 lbs. air pressure. If no leaks appear, the job is well done, and the jacket can be placed in position and made fast, using just as little solder on the front side as possible, to make the job strong. As soon as the jacket is placed in position, the tool E, in Fig. 1, can be used to straighten the fins, as already described. The fins should be spaced, and if any of them are stretched until they do not hold their spacing, a drop of solder can be used to hold it to the tube. As soon as all fins are straightened, a blacking should be used on the fins and tubes; in fact, all parts except the brass parts should be polished. For this purpose a liquid stove polish will answer well, and can be placed with a long bristle brush, as it will be impossible to get the inner tubes blackened unless a long brush is used. It is a good plan to place the radiator over a pan, and pour the blacking back and forth through the fins and over the tubes, that all may be blackened alike, for the job will not look well, no matter

Digitized by Google

how well done, with the outer row of tubes blackened and the inner ones spotted with blacking.

Now that the blacking is done, we are ready to polish the brass parts, and finish the job, to pass the inspection of the anxious customer. With a thin instrument, scrape all solder which is not necessary, from the seams on the front of the radiator, and make them look as well as possible. To polish the brass, use a good brass polish; or in case none is at hand, a weak solution of muriatic acid and water, with a little rubbing, will answer the purpose very well.

In case the radiator has a few leaky tubes, and not enough to pay to replace with new, we can repair as shown in Fig. 5. Here we have a radiator with two or three leaky tubes, and to get to these we will separate the fins, as shown in the illustration. With the use of the hook-nose soldering iron, the tubes can be soldered successfully. After soldering and testing, the fins can be slid back to their position, and the tool used to straighten the fins up. This job should be blackened and polished, and made to look just as neat as possible, as the customer will then be satisfied with the job and will say: "I had it repaired or rebuilt by Mr. So and So;" but if it looks half finished, he will say it was patched. See the difference?

Two men in the same town or city may be repairing radiators, but the man who takes pains in the finishing touches, as we call them, is the fellow who gets the work, although the balance of the work may not be as well done as the one left roughly finished. In this day and age of the world, the outside appearance goes a long way with the average man, whether it be on a radiator or some other part of the car.

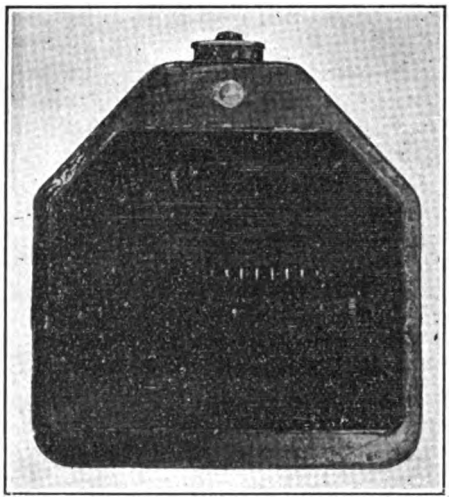

Fig. 5.

A very good soldering acid can be made by taking muriatic acid and cutting in it all the zinc that it will cut, setting away to settle. After settling, strain it through a cloth, dilute with half water, and place in a jar for use. For soldering tubes, where little solder is needed, I find the wire solder works quite a little better than the bar solder, as less is spread over the surface where it is not wanted.

A leather washer underneath the metal washer will often remedy a tendency to rattle, and will give an elastic compression that will avoid stripped threads where the bolt is rather small for its work.

DRY BATTERIES.

Their Evolution and How They Can Be Made to Give Good Service.

BY SYDNEY F. WALKER, M. E.

No. 3.

It will be understood that the quantities employed in any particular battery cell, have to be proportioned to the current the cell is intended to furnish; in other words, the larger the current that is to be supplied, particularly if it is to be supplied more or less continuously, the larger must be the quantities of the different substances, and the greater must be the care taken over the points mentioned. In all chemical work, and particularly where electricity takes a hand in the game, hydrogen gas performs its work in depriving the oxide of manganese of its oxygen, and in forming water, thereby reducing, and with a proper proportioned cell, neutralizing the back pressure set up; but the action does not cease there. When a current is passing through any battery, in which a liquid is employed, there is an actual transportation of the substances contained in the liquid, in the direction in which the current is going. In any galvanic battery, the current passes from the zinc plate to the copper or carbon plate inside the cell, and back from the copper or carbon plate to the zinc plate outside the cell. A certain confusion arises in the nomenclature of the parts of a battery from this fact. Thus, the copper or carbon plate forms the positive pole of the cell, because the useful current issues from it; but the plate itself is really the negative plate of the cell. It is the zinc plate which does the work, and which is the positive plate of the cell. Therefore within the cell, current passes from the zinc to the copper or carbon plate; and the return current enters at the zinc plate. In passing through the liquid contained in the cell, it decomposes them, certain elements such as oxygen, chlorine, an acid radical, and others, turning towards the zinc plate, the hydrogen metals, including the hypothetical metal ammonium, passing towards the carbon or copper plate. It will be remembered again, that the current which any battery will furnish, depends directly upon the pressure at the terminals of the battery, and inversely upon the electrical resistance opposed to that pressure. The resistance opposed to the pressure is made up of two quantities; that of the wires, etc., through which the current passes to do work outside of the battery, and the resistance of the liquid, the porous diaphragms, etc., inside of the battery. When porous diaphragms are used, their resistance is very high when the cell is first put into service, because the pores of the porous cell are filled with air. As the liquid penetrates and fills the pores, the resistance of the cell gradually decreases, and there is a very instructive point about the passage of the liquid in the direction in which the current is moving. If when a battery is first put into service, it is worked moderately hard for a short time, it will be found that its strength gradually increases, because the current carries the liquid into the pores of the porous cell, and gradually reduces the resistance of the cell as a whole. Later on when the secondary salts mentioned above, zinc ammonic chloride, and oxy-ammonic chloride are deposited in the pores of the porous cell, there is less and less room for the liquid to pass, and consequently the internal resistance of the cell is steadily increased, till when all the pores are filled, the cell

Digitized by Google

will give absolutely no current. In addition to this, as the deposit of the secondary salts over the small pieces of carbon and manganese goes on, they also gradually prevent the hydrogen from attacking the oxide of manganese, and from obtaining the oxygen it requires; so that the deposit of these salts tends to lower the pressure which the cell furnishes. The writer would like to draw attention to one point here, that is of importance where batteries are worked continuously, as when furnishing the current for lamps, or for the ignition of a number of cylinders of a fast running engine; the more continuous the passage of the current through the cell is, the less chance is there for the working back of the ammonia, and for the formation of the secondary salts. This means that providing there is a sufficient surface of oxide of manganese and carbon to neutralize the hydrogen gas as it is given off, the trouble from the secondary salts should be very slight.

There is another matter in connection with the working of wet batteries that is of importance, as showing how difficult is the designing of a dry battery. It has been found that the larger the amount of liquid in which the zinc is immersed, the better does the battery work; and the reason for this is, the cleaner the zinc plate is kept, the less is the amount of "polarization," or local action upon the zinc plate itself, due to the local battery formed by the oxide of zinc, and the zinc itself. So far as the zinc itself is concerned, the ideal working condition is obtained, when the oxide and chloride of zinc are dissolved in the liquid in which the zinc is immersed, as soon as they are formed. If no deposit is allowed to remain upon the zinc plate, the resistance between the zinc and the liquid is the lowest possible; while every molecule of zinc chloride or zinc oxide that is deposited upon the zinc, tends to increase the resistance to the passage of the current from the zinc to the liquid. It may be mentioned en passant, that a dry battery is not really a dry battery; it contains liquid; but it is in such a form that the cell itself can be transported without any of the attendant troubles, slopping the liquid, etc., that are usual with wet batteries. It will also be found that all the troubles that are met with in connection with wet batteries, are reproduced in dry batteries, and with the addition that there is very little liquid present to dissolve any salts that are formed.

And now as to the quantities, etc. One point that is of the very utmost importance, and which has the most definite bearing upon the working capacity of any cell, is the quality of the oxide of manganese. As the office of the oxide of manganese is to deliver oxygen, it will easily be understood that one pound of the mineral containing 95 per cent. of pure oxide, will have a very much larger quantity of oxygen to dispose of, to deliver at the call of the hydrogen gas, than a mineral say having only 30 per cent. of pure oxide. And this is not the whole story. With a mineral containing 25 or 30 per cent. only, the remainder of the volume is made up of foreign substances, dirt practically, that are not only of no use for oxidizing the hydrogen, but that give rise to considerable trouble in the working of the battery. Further, the foreign matter itself will offer a considerable resistance to the passage of the current, and it may easily happen that there is an electrical couple between some of the foreign matter and the pure oxide of manganese, or again between some of the foreign matter and the carbon. In any case the result of employing a mineral containing a low percentage of oxide, is that the battery will only do a very small amount of work. If a very large cell is made, with a very low grade mineral, a small current may possibly be taken from that cell, for certain work; but the large cell will only perform the same work, as a cell a fraction of its own size would have done.

The porous cell of the wet Le Clanche is filled in with a mixture of oxide of manganese and crushed carbon. For ordinary bell, signal and telephone work, the usual proportions are, equal volumes of

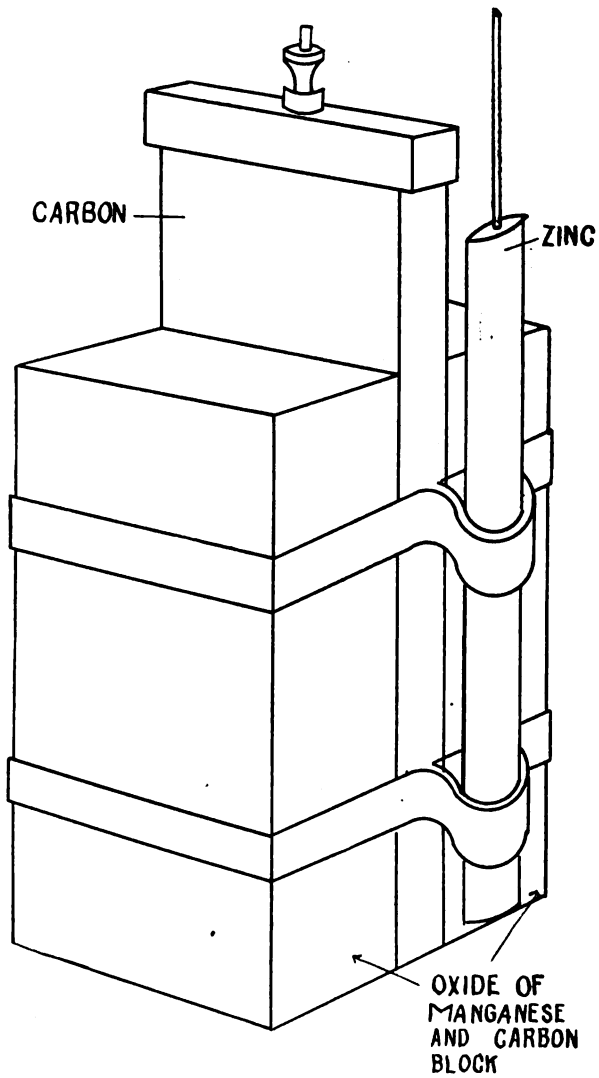

Fig. 9—Zinc, carbon and oxide of manganese and carbon for agglomerate Le Clanche cell.

oxide of manganese and of carbon, both being crushed to about the size of a pea, or of a lentil. About the size of a pea is the best, say ⅛ in. across the largest dimension. The reason for the admixture of carbon is to reduce the internal resistance of the cell. Oxide of manganese has a very much higher specific electrical resistance than carbon; and a cell therefore made up of only oxide of manganese would furnish a comparatively small current, though its staying power would be high. The resistance offered by the mass of granules of oxide of manganese would so increase the total resistance of the cell, that the current would be considerably reduced.

On the other hand, it is of the utmost importance that the proportion of carbon to oxide of manganese should not be too high. It is quite possible to reduce the resistance of the cell by increasing the propor-

Digitized by Google

tion of carbon, and also to reduce the cost of the cell, because crushed carbon is much less expensive than oxide of manganese. But cells so made, while they would furnish a larger current than others of the same size made with the proper proportion, would have less staying power. It may be taken that the smaller the proportion of oxide of manganese to carbon, the greater would be the current furnished, and the less the staying power.

Another point is the matter of the dust of both carbon and oxide of manganese. In preparing the material for the cells, the dust from both of these should be carefully sifted out. Another point that is of importance in the Le Clanche cell, is the size of the carbon plate. The larger the carbon plate, and the larger its surface, the better is the staying power of the cell. The carbon plate itself has a certain dissipating effect upon the hydrogen and ammonia gases; and it also has a certain ability to absorb those gases in its pores. It follows therefore, that the larger the plates, for both reasons, the better is the cell. The mistake must not however be made of providing a large plate at the expense of the oxide of manganese. There is a certain proportion between the two, that manufacturers of cells have discovered in the usual painful and expensive manner.

The carbon plate is porous, and its surface is rough; the secondary salts, oxy-ammonic chloride, and zinc ammonic chloride, are carried by the action of the current when the battery is in use, through the porous diaphragm, and right up to the carbon plate, and if other cells are broken open, it will be found that the carbon plates are filled with these salts; and very often, in old worked out cells, there is quite a smooth skin of the salts on the outside of the plates. The filling up of the pores of the carbon plate, and the formation of this skin upon its surface, tends to reduce the strength of the battery in two or three ways. In the first place the salts mentioned form with the carbon plate a secondary battery of their own, tending to oppose the pressure of the primary battery; and the carbon plate filled with the salts offers a much higher resistance to the passage of the current than the same plate when it is quite new, or quite clean. Carbon plates have been used over again in a few cases, by removing them from the porous cells, and dissolving out the secondary salts. It is rather a troublesome thing to accomplish. Some years ago an eminent professor in London suggested that Le Clanche cells might be renewed by passing a reverse current through them; by connecting them to some source of current, just as an accumulator is, leading the current from the outside source to the carbon plate, and causing it to pass through the cells, in the opposite direction to that in which the normal current passes. The idea was, that electro-chemical action would dissolve out the salts from the carbon plate. The present writer tried this some years ago, and he also tried various methods of getting rid of the secondary salts in the carbon plates, but while the cells made up with the renovated carbons stood fairly well for a short time, they had only a very short life. The renovated carbons were made up with a fresh oxide of manganese and carbon, and the cells in which they were employed were exactly the same in every respect as those in which new carbons were used; but the result was expensive and disastrous.

Another important point in connection with the working of the wet cell is the solution in which the zinc and practically the carbon plate and the oxide of manganese stand. The liquid was not to be saturated with salamoniac, and directions were given that salamoniac was only to be added, and in very small quantities, when it was quite sure that what had been placed in the cell previously had all been used up. In the writer's experience, he found that the best results were obtained when there was always some salamoniac at the bottom of the jar. He found that the cell worked best with a saturated solution, and so when there was some always at the bottom of the jar, the liquid took up what it required from the store there, and maintained its saturation. An important matter that used to be in dispute in those days was as to the question of adding fresh salamoniac to a cell in which the solution was evidently exhausted, or washing out the cell, and recharging it. Where cells had been constantly in use for some time, and it was clear that the solution was thoroughly exhausted, it was sometimes best to throw away the old solution, to wash out the cells, and start afresh with a new solution. In practice, however, it was not always easy to arrange to wash out the cells. Fresh water was rarely obtainable where the cells were in use, and for practical purposes it was found in the writer's experience, that the reserve supply of salammoniac at the bottom of the cell kept everything going as well as it was possible to do. Another important feature the writer found in his experience was, that the larger the amount of solution, the better.

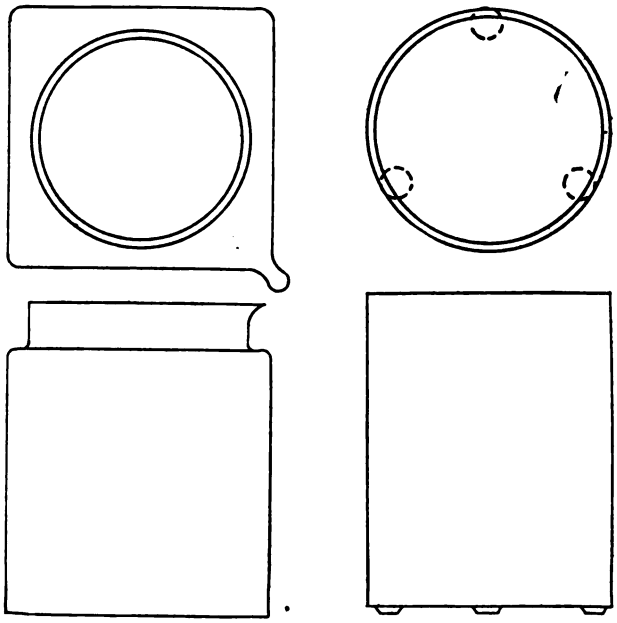

Fig. 10—Plans and elevations of two forms of jars used with Le Clanche cells; the square jar with a lip on the left and the cylindrical jar on feet on the right.

As will be understood, also, the zinc has a most important bearing upon the working of the cell. When the Le Clanche battery was first introduced, it was supposed that it was not necessary to "amalgamate" it; that is to say, to rub it over with mercury; but experience showed that zincs which were "amalgamated," stood up to their work much better than zincs which were not. In the first place it was absolutely necessary to thoroughly clean the surface of the zinc before it would take the mercury, and consequently the oil and dirt that were present upon the surface of the zinc rod, after passing through the

Digitized by Google

machine in which they were drawn, was removed; and it was pretty clear that even a small amount of acid, providing it was only a very small amount, left upon the zinc plate, did no harm. The great object to be attained in any primary battery in which zinc is employed, is the constant presentation to the active liquid, the solution of salamoniac in the case of the Le Clanche battery, of a perfectly clean, pure surface; and this was best effected by the process of "amalgamation."

The writer has detailed the construction and work-

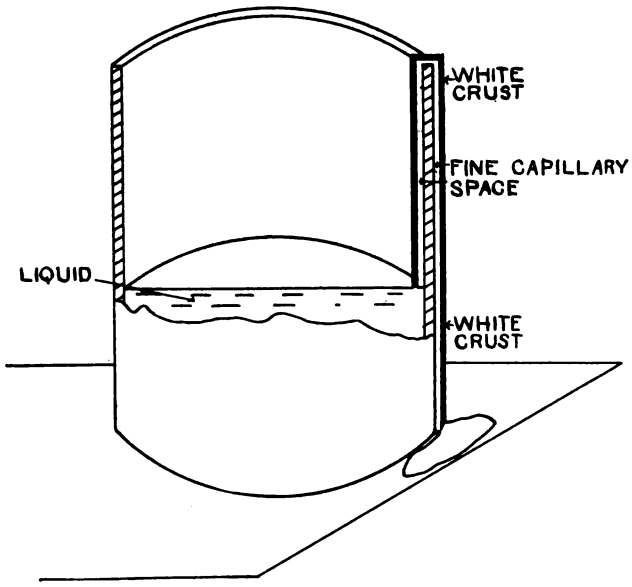

Fig. 11—Diagram showing how the white crust is formed on the inside and outside of Le Clanche cells and how it empties the jar of liquid.

ing of the wet Le Clanche cell, because it has a very exact bearing upon the working of the dry cell. He has sketched the difficulties in the way of the preparation of wet cells, in order to lead up to the question of dry cells. The same difficulties arise with dry cells, but in a very much more acute form; and in his opinion the success which has undoubtedly been obtained with dry cells, is due to the close following of the principles in connection with the wet cells. Purity of all the materials is perhaps the most important of them all. A point that should perhaps be mentioned here is, one effect of the crystallizing out of the secondary salts mentioned above, the oxyammonic chloride and the zinc ammonic chloride. They expand in crystallizing, with the result that porous cells have frequently been burst. In the old days, men who did not understand batteries, used to look upon a burst cell as a bad one. As a matter of fact, bursting the porous cell often gave it a fresh lease of life. In the development of the wet Le Clanche cell, there was another form introduced, which led indirectly up to the dry cell. What was known as the agglomerate cell was introduced, to overcome the troubles arising from the presence of the porous cell, the crystallizing out of the salts in the pores, etc. The "inside" of an "agglomerate" cell, the carbon plate, and the agglomerate blocks is shown in Fig. 9. It consists of a carbon plate similar to that which was employed with the porous cell, and two blocks of crushed carbon and manganese, that have been squeezed together by hydraulic pressure, and with the aid of some glutinous material, have been formed into blocks. The process is of course similar to that of making briquettes from coal dust for boiler firing, etc. In the agglomerate Le Clanche cell, the carbon that would have been placed in the porous cell in the form of small pieces about the size of a pea was crushed to a fine dust, and the oxide of manganese was also crushed to the same consistency. The two were thoroughly mixed together, in the same proportions as with the porous cell, viz., equal quantities by volume were mixed together; and the blocks were moulded in a die, in the same manner as bricks are made, with the aid of some glutinous substance. The blocks were held to the carbon plate by a couple of india rubber rings, and an eye was formed in each rubber ring as shown, for the zinc plate. The agglomerate cell furnished a larger current, it did more work, but it had not as long a life as a well made porous cell Le Clanche. The same trouble that has been mentioned above, in connection with the secondary salts, interfered with the working of the agglomerate cell. The secondary salts were deposited upon the surfaces of the agglomerate blocks; and the glutinous substance that was employed to hold the dust together, was attacked by the secondary salts, and as a result, the resistance of the cell as a whole increased very much, and the agglomerate blocks were rendered useless in a comparatively short time. The agglomerate blocks might be resuscitated by washing in hot water, so as to dissolve all of the secondary salts, but apparently they found their way right in between the pores of the block. At the finish, it will be remembered that the block would be porous to a certain extent, and that as the glutinous substance that was employed to hold the dust together was dissolved out, or pushed out, the secondary salts would find their way into the spaces vacated by the glutinous material. The result was that the agglomerate cell was not very satisfactory. No attempt was made to use cylinders of zinc enclosing the agglomerate blocks; it was found that the zinc rod was quite sufficient.

Problems in Constructing a Dry Cell.

The writer has gone very carefully into the details of the working of the wet cell, in order to lead up to

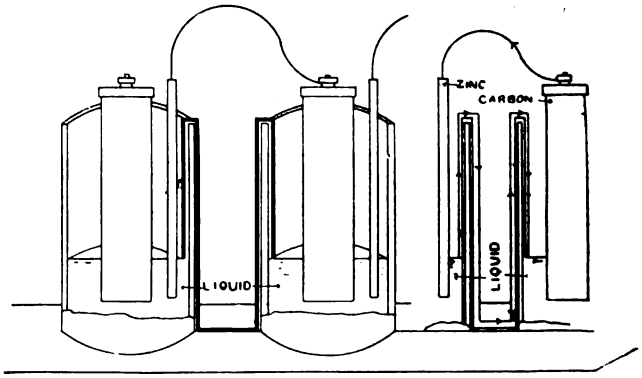

Fig. 12—Diagram showing how the white crust shown in Fig. 11 and the liquid in the capillary space inside the crust form a path for a small leakage current between adjacent cells.

the problems involved in the building of a dry cell. The first dry cell was introduced some 30 odd years ago. It was hailed with delight by a number of electrical engineers, but unfortunately it was a failure, because the inventor apparently had not had sufficient experience with the wet cell; he did not fully realize the difficulties in the way of working the wet cell, and how much they were increased in any form of dry cell. It was obvious, when the dry cell was first introduced, that it would be an enormous advantage to have only dry cells. The wet cell, though it did its work very well, providing that

Digitized by Google

its size was sufficient for the current it was to supply, often gave a considerable amount of trouble from causes over which it was difficult to exercise control. It was necessary sometimes to place the battery in a warm atmosphere, say in an engine room underground, where radiation from the cylinders, and occasional steam leakage rendered the atmosphere warm and moist. The result was, that the battery box became moist to a certain extent, and the salammoniac in the cells evaporated, and was deposited upon the outsides of the jars. Two forms of jars were employed with Le Clanche cells, shown in Fig. 10. A square glass jar, with a recess at one corner for the zinc. This recess facilitated the connections between adjacent cells. There was also a lip to the jar as shown. The other form was a plain earthenware jar. In one form, which the writer

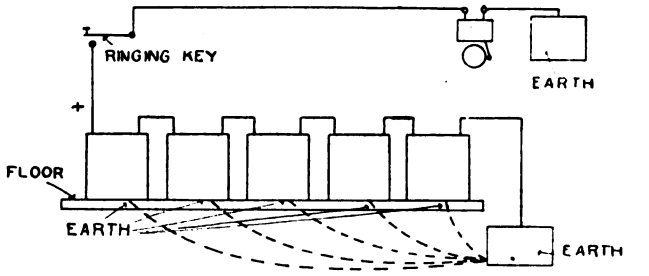

Fig. 13—Diagram showing path for leakage current from the battery to the ground.

very much favored the earthenware jar had three feet underneath the bottom, which raised it slightly above the bottom of the battery box. The feet were merely lumps of clay, roughly hemispherical, dabbed on when the jar was spun, but they had an important effect as will be seen later. The evaporation of the salammoniac solution from the inside of the cells went on continuously; it was deposited upon the outside of the jars, in the form of a white crust, the outsides of the jars being comparatively cool; and it gradually found its way to the bottom of the box. When the outer crust reached the bottom of the box, a syphon was formed by the capillary space inside of the crust on the outside of the jar, and also on the inside of the jar; and as the longer leg of the syphon was on the outside, the inside of the jar was gradually emptied. This is shown in Fig. 11. A further result that followed was, a path was formed for the current by way of the liquid salammoniac deposited upon the bottom of the battery box, and a leakage current was passing continuously from the carbon plate of one cell, to the zinc plate of the one to which it was connected in the ordinary way, as shown in Fig. 12. The quantity of current passing out from each individual cell by this leakage path was small, but as it was always flowing, it reduced the available capacity of the battery very quickly. The oxide of manganese was subject to a steady drain of oxygen, and the salammoniac in the jar was also subject to a steady drain; while the liquid in the jar was being steadily decreased. The result was that batteries in positions like the above, took a great deal of looking after. The difficulty was partly met by the three feet mentioned above, and shown in Fig. 10, upon which certain earthenware jars rested. It was also partly met by greasing the lips of the jars well, particularly the glass jars; but nothing of this kind appeared to be permanent.

Another trouble arose with wet cells in a battery box; it was often necessary to place the battery in a wet position. The box got very wet, there was the same leakage path for the current from cell to cell, as described above, and shown in Fig. 12; and there was also a leakage path for the current sent out by the whole of the battery, as shown in Fig. 13. It will be seen therefore what a boon the dry cell was looked upon, when it was first introduced. And so much was this felt, that long before it reached its present condition, it was largely used for telephone bell and signal work, notwithstanding the fact that the dry cell as a whole had to be renewed fairly frequently.

(To be continued.)

BATTERY CHARGING.

Something That Requires Care, Close Attention and Knowledge of Conditions.

The common lead accumulator, secondary or storage battery, as it is variously called, consists of two or more "formed" lead plates immersed in dilute sulphuric acid as electrolyte. Lead is chosen as the plate material, since the electrolytic action takes place readily, and, further, may be almost indefinitely repeated without serious loss of efficiency, the electrodes, lead peroxide, and spongy lead also yielding a fairly high pressure, namely, from 2 to 2.2 volts.

When accumulator plates are properly formed and the cell has received its full charge the whole of the lead sulphate that has formed on the positive plate during a discharge, as far as the acid has access, is changed into lead peroxide, while the negative plate is reduced to pure spongy lead.

On discharge the process is exactly the reverse, and the plates lose their sharp color and become flatter in appearance, the color of the plates becoming more alike, which in itself is a good indication as to the condition of the cell. It is necessary to understand that, when the positive plate appears flat and brownish in hue, lead sulphate has coated the active material and the cell has done all its available work. If allowed to remain on the plate, or if the charge be neglected, this sulphate will permanently affect the positive; it is important, then, to charge fully as often as required.

The decrease in density on discharge is due to the production of water in place of some of the acid in the electrolytic, the reverse proceeding, of course, taking place on charge.

During discharge the materials on both plates expand greatly, and if the expansion be not allowed for, the plates will break up or buckle. Such action tends to make the active material leave the plates, and in addition to the danger arising from possible short circuits, the capacity of the cell is much reduced. On this account it is necessary to design the plates in such a manner that the expansion is fully allowed for, and to prevent short circuiting by the installation of efficient separators. In addition, a "mud" space should always be provided at the bottom of the cell in order that any material leaving the plates may settle without risk of short circuiting arising.

During the charging process a gradual change takes place in the active material on the plates, the lead sulphate coating the plates, when the latter are in a discharged condition, being converted into lead peroxide on the positive, and spongy lead on the negative when the charge is complete. At this stage

Digitized by Google

"gassing or boiling" sets in, due to the gas formed bubbling through the liquid. Charging should always be continued until the cells gas freely—until the plates have given back all the acid to the solution, and the charging current causes no further rise in the density of the electrolyte.

This condition is easily observed when the battery is being charged apart from the car, but when otherwise, the driver must in general rely upon his voltmeter indications to furnish him with particulars of the state of charge. With the engine running and the dynamo charging, 2.5 volts per cell may be taken as an indication of a complete charge, the charging current, of course, being normal. Thus, 15, 10, 7.5 volts for a 6, 4, or 3 cell set will mean that the batteries are fully charged.

A further test may be made by switching the lamps on to the battery only, when each cell should yield a pressure of approximately 2 volts. The brightness of the lamps during this test will also be an indication of the state of battery as regards charge. When the charge is complete, switch off the dynamo, but always switch on again when the lights are in use.

The maximum current rates during charge, according to one authority, should not exceed 8 amperes per square foot of positive plate area, although in exceptional cases as much as 12 amperes may be allowed. This allowance, it should be noted, refers to plate area, so that both sides of the plate must be included. It is quite a simple matter to ascertain the area of the plates if the cells are assembled in celluloid boxes, for the number of plates may readily be counted and the total area ascertained. A charging rate is recommended of about two-thirds of the maximum stated by the makers. A good rule is to allow one-tenth of the stated capacity of the battery in ampere hours, a 60 ampere-hour accumulator requiring a charging current of some 6 amperes.

To test the agreement of the various rules a 60 ampere-hour battery was examined. Six positives were found to be fitted each 15 square inches in area. The total plate area was thus equal to 90 square inches (one side only), or 180 square inches reckoning both sides of the plates. Applying the first rule and taking 8 amperes per square foot as the charging rate, the latter is found to equal 10 amperes maximum, two-thirds of which gives a normal charging current of approximately 6 amperes. The second rule gives 9 amperes maximum, or 6 amperes as the normal charging rate, while one-tenth of 60 gives 6 amperes for the third rule. Thus, to avoid unnecessary trouble, if one-tenth of the capacity be allowed the charging current will be correct.

Danger of Too Large a Current.

Too large a charging current causes rapid boiling of the electrolyte before the charge is complete, the surface of the plate being insufficient for the current to act upon. The current is wasted, simply decomposing the electrolyte and heating the liquid, while if the paste on the plates is at all loose the rapid boiling of the electrolyte and the intense agitation may cause much material to be removed. Buckling is very likely to ensue, especially if the positive be in a bad state, when loss of paste and short circuits may result.

The motorist should, therefore, examine his battery, and having ascertained the correct charging current, compare this with the value shown by the ammeter when the car is running and the cells being charged. Variations in the charging current are an indication of an unusual occurrence, and should be inquired into immediately.

A low ammeter reading is an almost sure sign of a slipping belt, while a fluctuating reading may result from a belt, which, although too slack, drives correctly at low speeds but slips at high ones. Worn brushes may result in a decreased dynamo output, and they should be examined if the belt be found in order. The setting of the brushes should, however, never be interfered with, for in many machines the setting is vital from a regulation point of view.

If badly installed, the batteries may jump about when the car is in motion, with the result that a connection may become loose or broken. This condition will be indicated by an incorrect ammeter reading or by violent fluctuations in the light intensity. The car should then be stopped and the connections attended to. If a short circuit occurs the fittings to accessories should be disconnected in turn until the trouble is located. The discharging current, as mentioned previously, is limited by the lamps, etc., installed.

The normal discharge rate should, as far as possible, equal that employed during the charging process, but, of course, in starting batteries this is an impossibility. A starting battery is subjected to very severe stresses when in service, and it should be used as sparingly as possible, and an inquiry instituted if the engine fail to start almost immediately. Cases have occurred, for example, in which the battery has been ruined through the driver neglecting to turn on the gasoline, and it is therefore, more than ever necessary to keep a watchful eye upon the installation.

For ordinary purposes a maximum discharge of two or three times the normal charging rate may be allowed. Haphazard charging and discharging frequently results in the ultimate destruction of a battery, for the cells, although receiving numerous small charges, may be continually worked in a partially discharged state and then left like this for lengthy periods. The condition of the cells should, then, be ascertained before starting out, and then, if necessary, they should be charged up fully or until the voltmeter registers 2.5 volts per cell.

Care of the Belt.

From N. G. Near, New York.—The belt used for driving the fan or pump is a thing the average automobile driver overlooks—perhaps because belts seem to be such simple things. Well, they are simple enough, but they nevertheless require a little care. Don't allow them to become dry and hard. Keep them just right in tension—not too loose and not too tight. It is all right to put a little castor oil or neatsfoot oil on once in a while to keep them properly moist and slip proof. Better still, use a regular belt preparation, but rather than use nothing at all I recommend one of the above named oils. Don't use too much.

The same applies to leather universal joints, such as are now coming into common use. Apply oils or belt treatment with a brush, let it penetrate into the leather, and the leather will thereby be toughened, enlivened, and made more durable.

GARAGES AND REPAIR SHOPS.

Buildings, Lighting, Heating, Pits, Machines and General Arrangements.

From "Automobile Repairing Made Easy," by Victor W. Page. Published by The Norman W. Henley Publishing Co., New York.

(Copyright, 1915, by The Norman W. Henley Publishing Co., New York.)

As an example of the amount of space allowed in a building devoted to both a garage and repair business the floor plans of a garage located in a city of forty thousand inhabitants is presented at Fig. 1. This building has a frontage of 74 feet and is 150 feet deep. The front faces a main street and is occupied by a sales room 30 feet square in one corner and a main office of the same size in the other corner. The sales room has an attractive show window across the entire front and the other departments are also liberally provided with windows. The plant has five entrances, the main entrance at the front, which is 14 feet wide, two to the repair department, one at the rear to the main garage and one in the room set apart for the demonstrating car. All entrances measure 14 feet across and are amply high to permit the entrance of the largest motor truck. The building is of brick and concrete construction and is two stories in height at the front. The second floor front is occupied by the tire repair department and the stock room. Skylights over the repair department and the garage proper furnish plenty of light from above.

The floor space on the main floor, back of the office and sales room is therefore divided into three sections. The repair department is 30 feet wide by 120 feet long and is situated to the rear of the office. The garage proper is to the rear of the show room and is 44 feet wide and 120 feet long. The repair department is sufficiently large to employ 18 men. The building is heated by steam which is furnished by a heating plant in the basement underneath the main office.

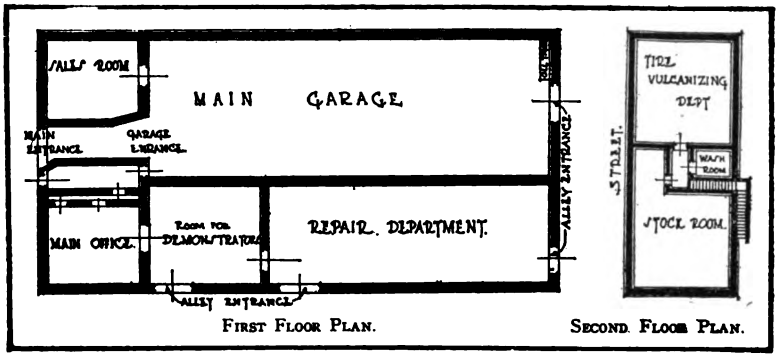

Fig. 1—General Plan.

The floor plan at Fig. 2 is that of a small building devoted exclusively to repair work and is suitable as a design for a shop to be placed at the side or rear of a garage. This building not only offers ample room to work on seven large cars but also provides for a complete machine tool equipment and ample space for office and stock room furniture. There is but one entrance, that being located at the front of the plant. The dimensions of the building and the arrangement of the various departments are so clearly shown that further comment is unnecessary. Floor plans are also given at Figs. 3 and 4 for a medium size service station, while a large departmentized repair shop is shown at Fig. 5. A medium size repair shop having a commendable arrangement of machinery and still leaving ample space for work-

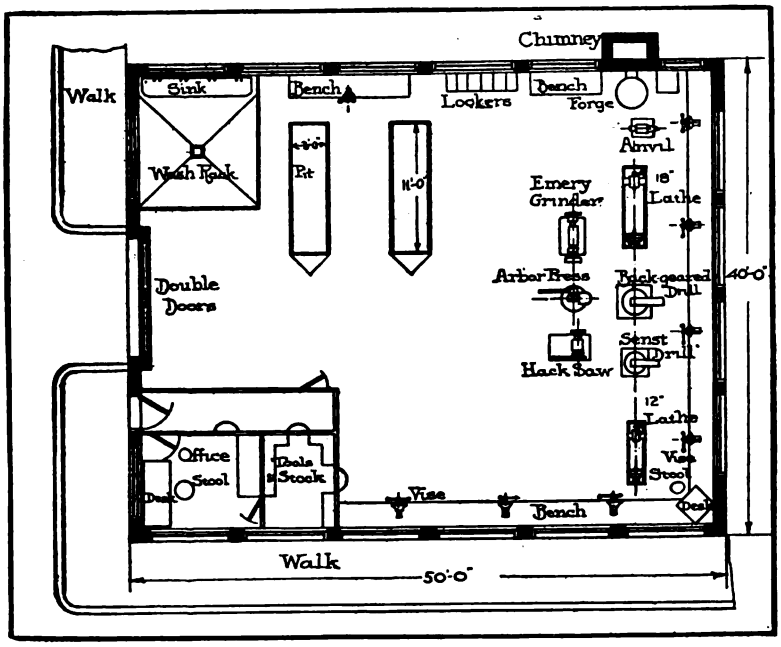

Fig. 2—For Repair Only.

Digitized by Google

ing on a good number of cars is shown at Fig. 6. In many large cities it is necessary to use buildings having more than one story on account of the value of land in business or manufacturing sections.

A typical arrangement of a converted factory building that has worked out fairly well for a service station is shown at Fig. 5. This is operated exclu-

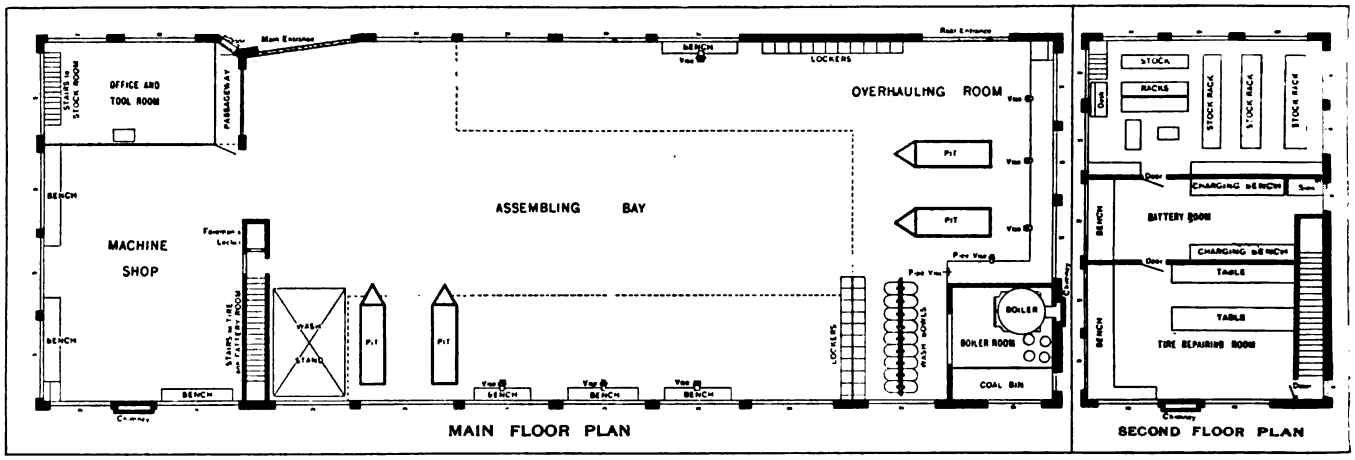

Fig. 3.

sively as a repair shop and has complete facilities. The building is of brick and while not as well adapted for motor car repairing as the specially planned structure at Fig. 6 is, it has been remodeled to good advantage. The building is 165 feet long and 36 feet wide inside the walls. Considering that the building is an old one built before the days when an intermediate room 28 feet long into which the elevator leads that is also used for assembling and overhauling purposes. The remaining small room on the ground floor which is 25 feet long is divided into three parts, one being used for an office, the others for stock and tool rooms, respectively. Nine large pits are provided on this floor and there is also ample bench room. This ground floor assembly department is devoted to work that does not involve taking down a car to any extent such as fitting various accessories, tuning or adjusting engines, repairing clutches, brakes, axles, etc., and other work that will not lay up a car for more than a few days. There is a large door at one end to permit cars to enter

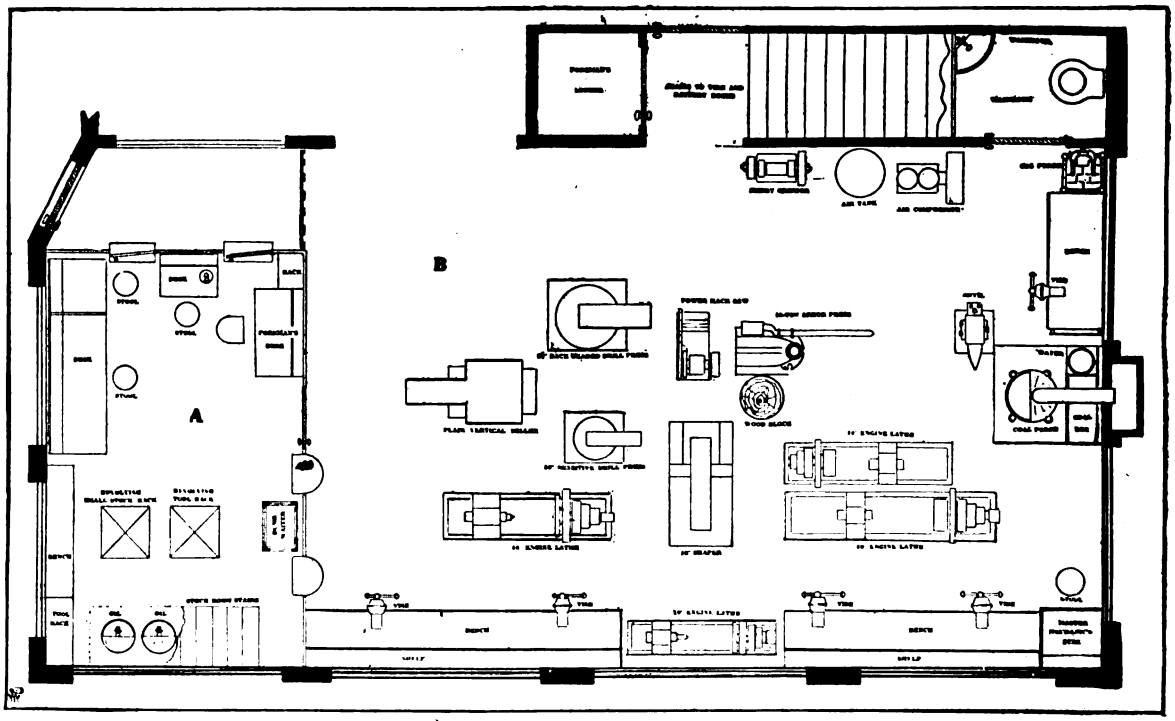

Fig. 4—For a Medium Size Station.

the provision of ample light was considered one of the essentials, it is fairly well lighted during the day as the walls are pierced with many small windows. At night a large number of Tungsten lamp groups of high candle power furnish the general illumination. Both floors are divided into three rooms, the largest 104 feet long being used as an assembling and storage room on both floors. On the lower floor there is directly from the street and a smaller entrance at the other leading directly into the passageway in front of the stock room counter over which the patrons are served. There is also a large door opening into the rear of the elevator, permitting cars to run on the elevator when this is in its lowest position either from the shop interior or from the street.

The upper floor is divided in much the same ma-

Digitized by Google

ner as the lower one, the largest room being used for overhauling purposes, the 36 by 28 feet room is used as a machine shop while the small room over the office and stock room is used as a forge and tinsmith shop. A large skylight in the roof of the blacksmith shop gives much needed light on the anvil and bench. There are no pits in this floor but as is the case with the one below, there is an overhead track extending the full length of the room for traveling chain falls attached to the ceiling. The equipment of the machine shop is very complete and enough tools are provided so that it is possible to duplicate any part of any automobile. The equipment shown at Fig. 6 is also very complete.

Lighting and Heating.

It is apparent that any system of illumination that involves the use of a naked flame introduces an item of fire risk that is very undesirable in a building where the fumes of gasoline are present. Electricity

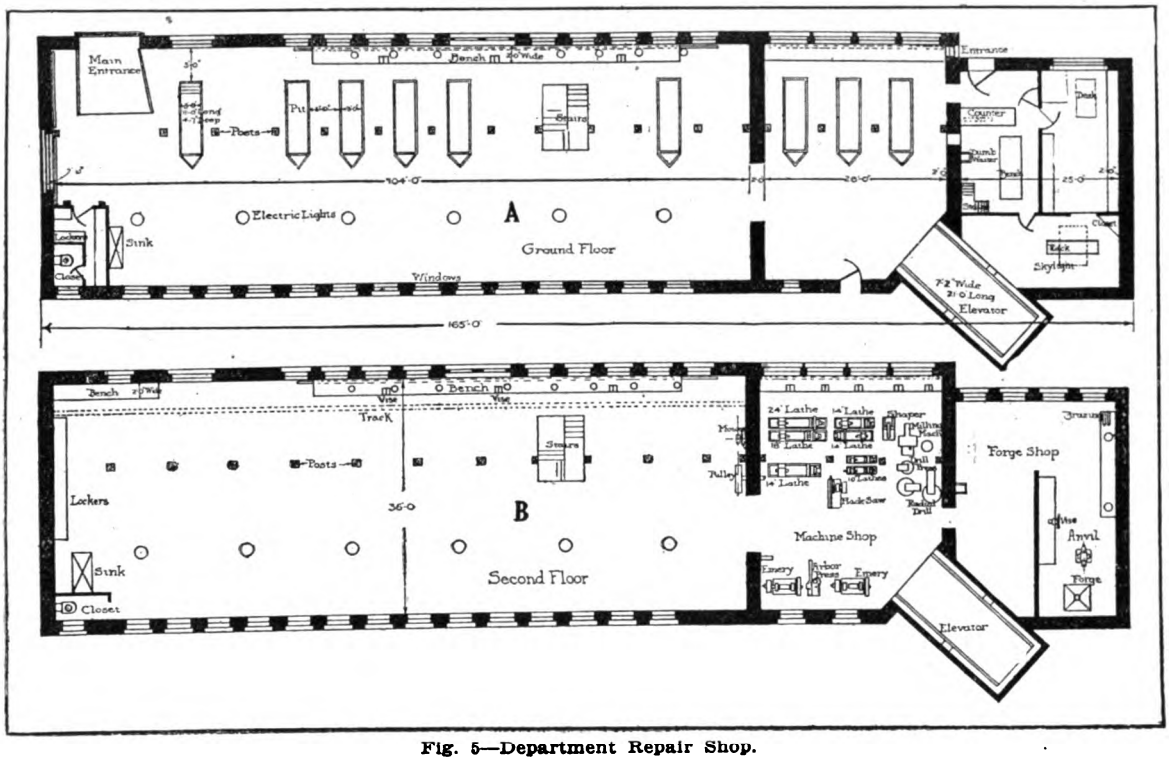

Fig. 5—Department Repair Shop.

is not only the safest method of lighting but the Tungsten lamp is the nearest to sunlight of the artificial radiants. Where electricity is available it will be poor economy to use other means of lighting, except for general illumination as by groups of incandescent mantle gas lamps. For individual lighting the electric lamp is the most suitable because it is safe, compact, clean, does not give out much heat, is portable and can be used in any position. There is no other means of artificial lighting that permits one to obtain all of these desirable requirements in combination.

It is very important that the workrooms should be kept at comfortable temperature during cold weather. About 75 degrees Fahrenheit is usually considered correct, though it may be lower than this if the men are engaged in active labor. In the machine shop where men must stand quiet much of the time, the temperature should be higher than in the erecting room, where they are constantly moving around and handling parts, this tending to keep the blood in circulation.

The back shop shown at Fig. 3, A, has two pits, three and one-half feet deep, four feet wide and 14 feet long. The edges of all pits should be sharply defined by a surrounding frame of two by four scantling, this being a guard to prevent the wheels rolling into the pit while manoeuvering a car about it.

Machinery for Small Shops.

The amount of machinery used in repair shop equipment will depend entirely upon the size of the shop and the character of the work it caters to. The requirements of the average small shop will be met very well by the use of a 16-inch screw-cutting lathe, a sensitive drill press, an emery grinder or twin wheel stand, and a forge outfit. If all classes of work are to be attempted, a small shaper will be found very useful, as much of the work that can be done on a milling machine can also be accomplished on the shaper, which is a less costly machine tool. In all repair shops, irrespective of size, the lathe is really the most important tool, and one good size machine of this kind should be included in the equipment of any repair shop worthy of the name, no matter how small. Practically all classes of machine work may be done on a lathe, as very efficient at-

Digitized by Google

tachments may be obtained on the open market that will enable a machinist to do milling, gear cutting and grinding on this universal machine tool. Drilling may be done without changing the lathe in any way. About the largest part to be handled in any repair shop would be an engine flywheel, as far as diameter is concerned, and the longest piece would probably be a six-cylinder crankshaft or live axle. It is not necessary to install a lathe capable of swinging 24 inches in order to have a tool available for work that would be unusual, as very effective results may be obtained by using a gap bed lathe which can be purchased at but slight extra cost over that of the regular tools. The advantages of this type of lathe will be considered in proper sequence. A lathe that will swing 16 or 18 inches will be sufficiently large for most shops, though it can be supplemented by a smaller size adapted for lighter work if the funds permit. In buying lathes, especially for a small shop where the machine tool equipment is necessarily limited, it is well to remember that small work can be handled in a large lathe much easier than large work can be turned in a smaller one, and where it is imperative that but one tool be purchased it will be the best economy to install a substantial machine. If a drill press is included, one that will swing 24 inches has been found large enough to handle nearly all parts of automobiles. The sensitive drill press is used for drilling small holes, and should have a capacity so that it will handle drills up to half inch diameter, at least.

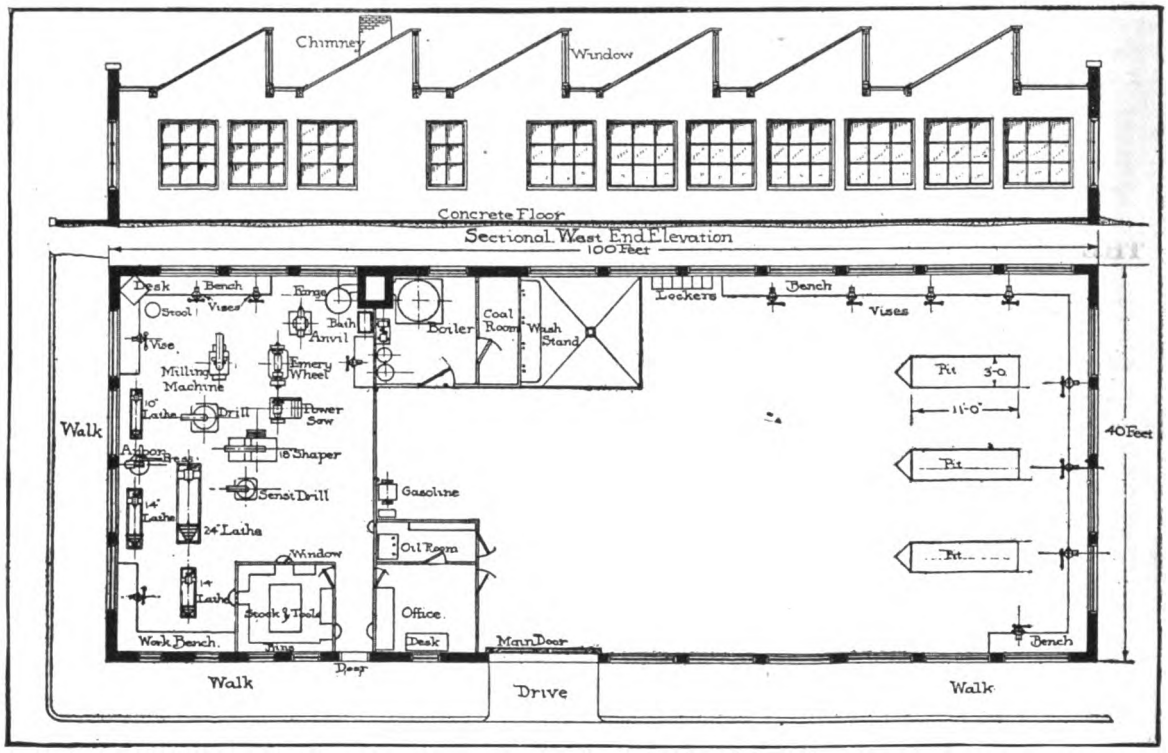

Fig. 6—Another Arrangement.

Equipment for Complete Repair Shop.

An unusually complete machine tool outfit is shown in the shop plans at Figs. 5 and 6. With an equipment of this nature all kinds of repair work may be accomplished economically and, in fact, the outfits shown are sufficiently complete so competent mechanics will be able to build an automobile without outside assistance. As the lathe is the king of machine tools, the major portion of the equipment consists of these useful machines. Seven lathes are provided, two being ten inch swing, three fourteen inch swing, one eighteen inch swing and one capable of handling work up to twenty-four inches in diameter. A universal milling machine upon which a wide variety of work may be done is a useful adjunct to the lathe. A milling machine can finish flat or irregular surfaces which a lathe cannot do unless fitted with a milling attachment. It will make Woodruff keyways or straight splines, it can cut gears, cams and do a variety of other work that cannot be done on the simple lathe.

A small shaper having about sixteen inches stroke is also useful, because it will do much of the work done on a milling machine and require simpler tools. While a milling machine has a greater range of work and will do it more economically than the shaper, the latter can be used to advantage in many cases where the cost of milling cutters would be much more than that of making the shaper tool and doing the work besides. Both milling machine and shaper should be provided, if possible. Three drilling machines are provided, one a sensitive drill for light work, the intermediate size, a back-geared drill press, and for extremely large work, such as drilling frames, boring cylinders, axle housings, etc., a radial drill is very useful, as it will handle any part of a motor car irrespective of size. A power hack saw, two emery grinders, one used for roughing purposes and the other for tool grinding, and an arbor press complete the equipment of this machine shop.

Power for the Shop.

Just as electric current is superior for lighting, it also has many advantages as a source of power. The electric motor is an ideal power generator, because it is clean, efficient, economical, easily started and stopped, compact and capable of standing considerable overload. It makes possible individual motor equipment of machine tools in large shops and can be used very effectively for driving the line shafting

Digitized by Google

of the smallest establishment, because it can be suspended out of the way on a platform hung from the ceiling or in the smaller sizes placed on a shelf attached to the wall or some convenient post. Where electric current is not available and where it is not profitable to install a generating plant, the gasoline engine is an economical method of supplying power. The marked advantage of electric current is that it may be employed not only for lighting, but for operating various portable drills, polishing machinery, air compressors, etc., and it also has a great advantage of generating current that can be used for charging storage batteries, which are now included in the equipment of all up-to-date automobiles, as a source of current for the electric self-starter and lighting system. Where electric current is not available from a municipal central station, a garage or repair shop of any size will find it more economical to install a generating plant and make its own electricity for lighting and power than to use a steam or gasoline engine which can only furnish power and then depend upon kerosene and acetylene lamps for lighting, which naturally increase the fire risk.

THE LEGAL SITUATION.

Things Car Owners and Drivers Are Advised to Read and Remember.

Liability of Owner for Defective Brake.—In an action by a chauffeur against his employer for injuries caused by the defective condition of the brakes of the car, it appeared that the chauffeur knew of this defective condition and that the car was liable to start itself at least two weeks before the accident occurred. The plaintiff was an experienced chauffeur. He had been engaged in operating automobiles for upwards of five years and the one in question for three or four weeks. If he knew that the brakes were defective, and by reason of that fact the machine liable to start of its own motion, then it was for the jury to say whether, by placing himself in the position which he did immediately prior to the time he was injured, he did not assume that risk. The jury found for the plaintiff. It was held on appeal that the verdict was against the evidence, and it was set aside. There was held to be another reason against recovery. In a populous city like New York, where thousands of people are in the street at all hours of the day and night, an experienced chauffeur, unless it be under exceptional circumstances, who runs an automobile in the street, knowing that the brake is defective, ought to be estopped, as matter of law, from recovering damages against his employer for injuries occasioned by such defect.—Marks v. Stolts, New York Appellate Division, 150 N. Y. Supp. 952.

Injury by Collision—Evidence of Intoxication.—Under New York Highway Law, Sec. 290, Subd. 3, the operation of a motor vehicle by a person in an intoxicated condition is expressly prohibited, and an innocent person injured in consequence of a violation of this statute is entitled to his civil remedy for damages. In an action for damages to a taxicab from the defendant's negligent operation of his automobile, it was held that evidence that the defendant was intoxicated, was admissible, and improperly excluded, especially when a disinterested witness testified that the defendant's car was going in a wabbly condition at 55 or 60 miles an hour, that the taxicab was struck by the automobile when near the center of a street which it was crossing, and that no collision would have occurred if the defendant had directed his car to the rear of the taxicab.—Lincoln Taxicab Co. v. Smith, 150 N. Y. Supp. 86.

Validity of Village Speed Ordinances.—By section 288 of the New York Highway Law, village authorities are authorized to limit the rate of speed to 15 miles an hour only upon the public highways, and then only by passing the requisite ordinance, posting signs conspicuously on each main public highway and filing a copy of the ordinance with the Secretary of State. In proceedings for running an automobile through a village at the rate of 23 miles an hour, in violation of an ordinance limiting the speed of vehicles "within the corporate limits of the village" to 15 miles an hour, it was held that the ordinance was unauthorized. The village had no legal right to so ordain. It was limited by the statute in this regard to supervision of the public highways.—People v. Bell, 148 N. Y. Supp. 753.

New York City Regulations.—In a prosecution for driving a motor vehicle at a speed exceeding 20 miles an hour in violation of the ordinance which took effect June 1, 1913, (Section 1), regulating speed in the city of New York, the question arose: What is the lawful rate of speed at which an automobile may be operated in the City of New York in a developed and closely built up section? The court construed the section as follows: It is permissible to operate any motor vehicle in a developed and closely built up section of the city, at a rate of speed not exceeding 15 miles an hour. If any of the vehicles are operated at a rate of speed exceeding 15 miles, and up to 20 miles an hour, such rate of speed shall constitute prima facie evidence of a rate of speed and manner of driving prohibited by the section. If a person is arrested upon a charge of driving any of the vehicles at a rate of speed exceeding 15 miles and up to 20 miles an hour, such person may rebut the presumption that he drove the vehicle recklessly or negligently or in a manner so as to endanger the life or limb or property of any person. Upon establishing this, the defendant should be discharged. The driving of any motor vehicle at a rate of speed exceeding 20 miles an hour constitutes a violation of the section, and a person charged therewith cannot be permitted to offer any evidence or rebut the presumption of reckless or negligent driving. As the defendant operated the automobile at a rate of 23 miles an hour in a developed and closely built up section of the city, he was held properly convicted of a violation of the section of the act.—People v. Reutiman, 148 N. Y. Supp. 612.

Violation of Speed Ordinance.—Section 2 of the New York City ordinance in relation to speed regulations contains two separate and distinct offenses, one forbidding the turning of corners at a greater rate of speed than four miles an hour, the other forbidding the passing or approaching within eight feet of a street car which has stopped to take on or discharge a passenger. It is held that the owner of an automobile, while riding therein, is responsible for the act of his chauffeur in committing either of these offenses.—People v. Colon, 148 N. Y. Supp. 321.

Liens of Conditional Vendor and Repairer.—In the sale of an automobile the purchase price was represented by two notes, each of which contained a stipulation retaining title in the machine to secure

Digitized by Google

payment. Possession passed to the vendee. Repairs being necessary, they were made by a mechanic, who returned the car to the vendee. On default in payment of the first maturing note the vendor repossessed himself of the machine by replevin. The mechanic brought suit against the vendor to enforce a mechanic's lien on the car for the repair bill, under the Tennessee Mechanic's Lien Statute of 1909. It was held that the mechanic's lien was subordinate to the lien of the conditional seller of the car. The court reasoned that placing the car in the possession of the conditional buyer should not be considered as a consent in advance to the subordination of the title retained for security for the payment of the purchase money, and the seller's intent, if any, to permit repairs and a consequent lien attaching to his interest should be manifested in the note contract, as otherwise the reservation of title would be deprived of a considerable element of marketability.—Shaw v. Webb, Tennessee Supreme Court, 174 S. W. 273.

Signalling Automobile Driver to Stop.—Missouri Motor Vehicles Law of 1911, Sec. 8, requires the driver of a motor vehicle on signal by raising the hand from a person riding, leading, or driving a horse or horses or other animals to bring such motor vehicle immediately to a stop. The driver of a team of mules attached to a wagon called to an automobile driver to stop, and a person riding in the wagon raised his hand as a signal to the automobile driver, but the driver of the mules did not signal by raising his hand. In proceedings for violation of the section it was held that the automobile driver was not criminally liable for failure to stop. The statute does not require the automobile driver to observe signals from persons other than the driver of the animals, and the statute, being both penal and criminal, must be strictly construed in favor of the defendant and cannot be extended beyond the plain meaning of the language employed.—State v. Wilson (Mo.) 174 S. W. 163.

Insurance Against Theft.—In an action on a policy insuring against loss of an automobile by theft by persons "other than those in the employment, service, or household of the assured," it is held that the insured had the burden of showing that the automobile was stolen by some one not in his employment.—Kansas City Regal Auto Co. v. Old Colony Ins. Co. (Mo.) 174 S. W. 153.

Fiscal Court's Authority to Purchase Automobile.—The Kentucky Court of Appeals holds that the fiscal court of a county which without authority purchased an automobile could not keep the machine and at the same time sue to recover the money paid therefor, but was bound to offer to return the machine to the seller. The court having no authority to purchase an automobile, it was held it had no authority to hire one, and could not become liable for the depreciation in value of one purchased without authority or the value of its use while retained by the court.—Miles Auto Co. v. Dorsey, (Ky.), 174 S. W. 502.

Representations in Sale of Automobile.—The buyer of an automobile is justified in relying on the seller's representations as to those parts not open to inspection, but not for misrepresentations as to visible defects. Under this rule he would be entitled to rely on representations that the machine had been rebuilt.—Morbrose Inv. Co. v. Flick, (Mo.), 174 S. W. 189.

TROUBLE-DEPARTMENT

This department is intended as a "trouble clearing house" for car owners, dealers and repairmen. Inquiries in relation to marine motors will likewise be answered as they are of interest to car owners and others who use the two-stroke cycle engine.

Readers are requested to make criticism and comments or to freely discuss any subject of interest to the automobile industry, and to add information of their own experience in remedying troubles.

Inquirers are asked to give the fullest information in every case so that replies may be made intelligently, and thus be of interest not only to the inquirer but to others.

1663 Faulty Ignition.

From W. E. Morain, Illinois.—I have a 1912, 4-cylinder Mitchel automobile, with low tension Splitdorf magneto and coil, 1913 make, and a Stromberg carburetor. I crank on the batteries and when I switch from the batteries to the magneto the engine will stop every time unless it is running at high speed.

Reply.—As the same make-and-break mechanism, secondary distributor, coil and wiring are used in both battery and magneto systems, it is plainly evident that the magneto does not generate sufficient current except at high speed. Such a condition is most likely due to a partial demagnetization of the magnets, or it may be that the primary magneto wiring is defective. In any case the proper proceedure would be to send the magneto to your nearest Splitdorf Service Station, which is in Chicago at 64 E. 14th street.

1664 A Hum in the Gearing

From Frank Revelette, Jr., Kansas.—I have a B 37 Buick touring car, 1914 model, that has a hum in some part of the gearing and I haven't been able to locate where it is. I wrote the Buick people about it and they told me it was in the differential; that it was a sprung gear and that I would have to get new gears, but I took the rear axle out and found nothing wrong with it. I keep it well oiled. Then I was told that it was my cam gears and that they were dry but I have kept plenty of oil in them, and to satisfy myself I put a lot of heavy grease in them, but it made no difference. It sounds in the transmission, but I have kept plenty of oil in it. In fact, I have had it running out around the propeller shaft so I know that it has plenty. Now, the way it does it is like this: When I drive about 8 miles an hour in high with the regular load you can hear it, then if I speed up it goes away until I get to 18 miles, then you can hear it again, then faster than that you cannot hear it. It is a growling hum and sounds only when in high gear. Now if you can give me any idea what the trouble is, it will be greatly appreciated, and I thank you in advance.

Reply.—We think that the Buick people were probably right when they told you that the trouble was probably due to the fact that the gearing had been sprung in some way. As to the humming or grinding occurring at a low speed and then going

Digitized by Google

away until you drive at a very much higher speed, this is due to what is termed by scientific people as "mechanical resonance." If you have a water faucet in your house you may notice that when you turn the water on slowly there is likely to be a vibration, which will stop when you turn it on more and perhaps resume when it is turned on full force. This is because the vibrations are what may be termed in unison when at a certain speed and are not in unison when it is at another speed. We do not suppose there is any way to stop this noise, except to first find exactly where it is and then purchase new gearing in place of it.

1665 **Magneto Trouble.**

From H. P., Delaware.—I have a 1913 touring car, which has been run about 6,000 miles. It has a Schebler carburetor and a Remy low tension magneto and coil. About four months ago it began to miss while running on the magneto at low speed and finally at times would not run at all on the magneto, but would run on the batteries. A repairman told me that the magneto was dead and would have to be remagnetized. I sent it and the coil to Philadelphia and they overhauled it and it has worked all right until a few days ago when the same trouble started again. At real high speed it will run on the magneto all right, but when I come to a road that is heavy enough to make it slow down, it starts to miss on all cylinders. If I switch onto the batteries then it runs all right in any speed. The cylinders have been taken off and new piston rings put on the pistons. Also the valves have been ground. If I come to a hard pull while running on the magneto and it misses, I can switch over even at slow speed and it takes right hold. If you can throw any light on my trouble it will be greatly appreciated.

Reply.—The magneto with which your car is equipped, is not a low tension magneto, for the coil is only used when ignition is by battery. Magnetos generate a stronger current at high than low speed. The strength of the current is also affected by the strength of the magneto magnets. In your case the magnets themselves may be at fault or there may be some other reason why they should become partially demagnetized twice within two years. There are two courses for you to pursue, have the magnets themselves renewed or have them remagnetized once more. In either case we advise that you carefully observe the ground wire leading from the switch to the chassis frame, and see that a good metallic contact is at both ends. The reason for this is that when the switch is in the "Off" and "Bat" positions the magneto circuit should be closed absolutely. Batteries sometimes discharge through the magneto wirings and if the flow is opposite to the direction of flow during the charging of the magnets, the result is trouble.

1666 **Coil Trouble.**

From Walter N. Lawson, Indiana.—Is there any way to tell if a coil is broken down without the use of another coil?

Reply.—You can usually tell when the condenser is perforated by the fused condition of the contact points. The only simple and absolutely sure way would be to try a known good coil, or try the coil in another car.

1667 **Moisture for the Fuel.**

From A. A. Kitto, Colorado.—I am interested in an attachment for carrying a quantity of moisture into a carburetor. It acts as a humidifier. What is your opinion regarding the introduction of moisture into a carburetor? Any space you can give to this question will be appreciated.

Reply.—If the moisture can be regulated to the speeds and needs of the engine it is an aid to carburetion. Its action is to make the pressure in the cylinders following the explosions more elastic, by slightly lengthening the period of greatest effectiveness. As a result moisture in the explosive charge should be more effective at low and intermediate, than at high speed. Large stationary gas and oil engines practically always employ water or watery vapor in order to be able to properly advance the spark without accompanying pounding. You will find that moisture taken in at the carburetor, however, will soon clog the air opening with frost, hence the custom to introduce it as near the cylinder inlet valve chests as possible, to prevent the formation of ice particles.

1668 **A Slipping Clutch.**

From A. U. Burque, New Hampshire.—The multiple disc clutch in my Hupmobile car slips once in a while, more so when warm. The clutch is in the case with the transmission and runs in medium oil—the same oil is used for the transmission gears and clutch. Will you tell me how to remedy the trouble?

Reply.—If your clutch has been giving good service for some time and now suddenly develops a tendency to slip, we would advise you first to drain out the old oil and inject a pint or more of kerosene. Then close the opening to the casing, start the engine, and with the gear in neutral position operate the clutch pedal so the kerosene may be thoroughly distributed. This will rinse and clear the mechanism of old and sticky oil. Then flush it out once or twice more with fresh clean kerosene and refill to the required amount with clean oil. If the clutch still slips after this treatment, an increased spring tension may be required. This can be obtained by tightening all the adjusting studs evenly all around.

The proper way to adjust this type of a clutch is to screw the studs back, or release them entirely from contact with the plate or mechanism inside the clutch casing, then screw them up carefully with the fingers until each one just begins to touch, which is indicated by an increase in the effort required. When each screw or stud has been turned up so that it just begins to touch the plate or mechanism against which it bears on the inside of the clutch casing, then with the aid of a wrench, give each screw a half turn forward and repeat, until the proper adjustment is obtained. The object is to give each screw the same number of turns and at the same time have them all move forward at practically the same time. If one was to give one screw five or six full turns and proceed to the next one and give it the same number of turns, etc., until all had been turned up the same amount, the same results might be obtained; but it is most probable that the job would not be successful, and perhaps damage to the internal mechanism of the clutch would ensue as a result of possible binding or cracking. On the other hand, if the studs were screwed alternately, little

Digitized by Google

by little, but no care given to the relative number of turns given to each, the springs or operating mechanism would most likely bear unevenly upon the disks, and a jerky, grabbing or slipping action of the clutch would result.

1669 **Irregular Running.**

From E. E. Shockey, Missouri.—I have a Studebaker "25" which is giving me a great deal of trouble. It will missfire and run very irregular on all speeds, first one time then another. It will run good for a short distance on high then all at once will commence missing, then perhaps will run O. K. again. It does not seem to miss on the same cylinder all the time. It also seems to do better with the throttle partly open than when the throttle is fully open. The engine runs very irregular at high speed but seems to pull very well at times. Have been having this trouble since last December, have had the engine overhauled, doing no good, new spark plugs, doing no good, and rewired entirely. Car has been run only 6,000 miles and has had excellent care at all times. An excellent garage man has been doing all the work on this car and he fails to find the trouble.

Do you think this trouble could be in the carburetor? Am pretty sure that it is not in the ignition system. It is a Holly.

Reply.—We are sorry for your sake as well as for other owners of Studebaker "25" cars, that you did not give us sufficient information from which to be able to give you desired help and assistance. There are many possible causes for erratic running, such as you describe, both in ignition and carburetion. If with the throttle fully open the result is too much gasoline, it looks as if the Holly carburetor needed attention, adjusting, or replacement. Late models of Holly carburetors are decided improvements over earlier models. You give us absolutely no information as to which model you have on your car. If, as you say, your garage man is unable to locate the cause of the trouble, and he is up-to-the-minute in mtaters pertaining to carburetion, he should be able to do better than we could be expected to do at "long range" with practically no information. It should not take a practical automobile mechanic very long to derive the cause of the trouble, providing he has the car before him.

1670 **Two Good Ignition Systems.**

From R. P. Johnson, New York.—Which would you advise me to install on my Ford car, an Atwater-Kent or Bosch magneto, to replace my present flywheel magneto?

Reply.—You are taking us at a serious disadvantage when you propound this query. We advise you, if you have not already done so, to write to the Atwater-Kent Machine Works and to the Bosch Magneto Co., for full information of their respective ignition systems for use on Ford cars, and incidentally tell each that you are undecided as to which will give you the better service. In both instances you will doubtless receive instructive replies and possibly they may be of value in determining for yourself.

1671 **B. Was to Blame.**

From G. S. C., New Jersey.—Will you kindly give me in your next issue your opinion of the following accident, which occurred recently on Asphalt State Road, in New Jersey?

A. & B. were traveling in the same direction, A. in the lead. In front, at their right, on the side of the road, a car was standing, headed in the direction they were traveling. As A. came almost alongside the standing car, the driver started up, and turned toward the middle of the road, thus partially cutting A. off. A car was rapidly approaching in the opposite direction. A., seeing that he had no room to pass, jammed on his brakes, bringing his car to a dead stop, thus avoiding a head-on collision; but he had no sooner stopped than he was run into by B., whose left headlight struck A's left rear tire. B's headlight was broken, while A's tire burst, and his left spring was bent, besides other minor damage done. B. said that A. was at fault, because he should have raised his hand, to indicate his intention to stop. A. said it was an emergency, and that his hands were fully occupied in bringing his car to a stop. A. claims that B. was at fault, because he was following too closely. B. stated that he was traveling 8 feet behind A's car, and could not see the car coming in the opposite direction. They both agree that they were traveling 12 to 15 miles per hour. Now, A's top was down, and A. thinks that B. had no right to be traveling as close behind him as 8 feet, or where he could not see what was coming in the opposite direction. Can one traveling 12 to 15 miles per hour be sure of stopping in time, in an emergency, if he is traveling only 8 feet behind another car?

Reply.—B. was clearly to blame. He should not have kept his car within 8 feet of A.'s car. The rule to not follow a car too closely is one of the oldest of automobile road rules. The car in front may be obliged to stop suddenly and without giving a signal, and if so an accident is almost certain to follow. In the case stated, the front car was obliged to quickly stop without giving a signal, and the inevitable accident followed. In traveling not more than 12 to 15 miles an hour, cars should not get nearer than 16 or 20 feet from one another, and in case of more rapid speed the distance should be greater. Although it is not so stated, we trust that before attempting to pass the car standing at the side of the road, A. sounded his signal. If he did not, he has no grievance against the driver of the car which cut him off and caused him to stop suddenly.

1672 **Passing Trolley Cars.**

From R. E. Schuman, Delaware.—To settle a controversy will you please decide the following: A claims that it is a violation of the penal code in some States to pass a trolley car being operated on a double track by turning to the left, while B claims that a trolley car should be passed by turning to the left just the same as one would pass a heavily loaded truck or other vehicle. They have agreed to abide by your decision.

Reply.—When one comes to consider that heavily loaded and slow moving vehicles are supposed to keep close to the right hand curb in thickly congested streets and that all vehicles except trolley cars, are supposed to turn to the right to pass to their left, it is not surprising that this controversy should arise. In some cities, New York for one, the police officers permit passing trolley cars by turning to the right, when it can be safely done, while in

Digitized by Google

others even if it were possible to do so without endangering anyone, the offender would be fined if apprehended. The proper side to pass a trolley car, if there is room, is by turning to the right, providing the track is not a single one, of course.

1673 **Regrinding Cylinders.**

From V. E. Harrington, New Jersey.—What would you call a fair charge for regrinding the four cylinders and fitting new pistons and rings of my 1913 Overland?

Reply.—Firstly, we do not want you or any other car owner to use this reply as a whip over any garage owner or car repairer, for we know by experience that it would be well nigh impossible, under present service conditions, to set a fixed or empirical rule over such repairs. There are manufacturers and others fitted up to grind cylinders and fit pistons and rings, who advertise to do this work for $10 per cylinder. This price, however, could not be approximated even, unless one were equipped to do the work and it would not include disassembling and reassembly.

1674 **Advancing the Timing.**

From M. L. Mead, Maine.—I have a Cadillac 8-cylinder car, new last February, which has been run between 12,000 and 13,000 miles. I have removed the thermostat governing the water circulation, advanced the timing one tooth of the timing gear, and never since have I had any trouble from overheating. The contact points in the ignition timing head are about burned out. 1.—What I would like to know is why advancing the timing tends to keep the motor cool? 2.—How long should a set of contact points last? 3.—How can I increase their life of usefulness?

Reply.—1.—You did not so state, although it is probably true, that advancing the timing by changing the meshing of the timing gears has decreased your fuel consumption, and probably has slightly reduced the power of the engine at ordinary running speed, and increased it slightly at high speed. The effect of opening the exhaust earlier would be to get rid of the hot products of combustion before so much of the heat could be radiated through the cylinder walls to the circulating water. We believe the regular setting of the valves in this model to be in the line of maximum efficiency at ordinary, rather than abnormally high engine speed. 2.—Very hard to calculate the expected length of life of usefulness. The manufacturers of the car should be able to approximate the total mileage. You should remember that for every mile traveled on high gear it takes approximately 10,000 revolutions of the engine, or 40,000 sparks. 3.—You could probably increase their life by occasionally changing the direction of flow of current. If the current flow is always in the same direction it carries the metal of the contact points from one to the other. In the operation of marine engines using make-and-break ignition changing the direction of flow is sometimes made every day in order to keep contact points from burning out too rapidly. Of course the waste from this source is much reduced if the condenser is ample to prevent arcing at the contacts as the circuit is broken.

1675 **Two and Four Cycles.**

From Byron Weems, Saskatchewan.—As a matter of fact I desire to know whether a two-cycle motor car engine ever has been manufactured which would show a range of speed from low to high to compare favorably with four-stroke design, and if not, why not?

Reply.—We do not believe that any two-stroke-cycle automobile motor ever has or will be produced, which can compare favorably, in fuel economy or speed flexibility, with ordinary four-stroke-cycle engines of modern design and construction. In the two-stroke-cycle the four separate functions, viz.: intake compression power, and exhaust are performed practically entirely during four separate reciprocations or strokes of each piston, which allows of a much longer interval of time to overcome the inertia of the explosive mixture and burned gases. In the two-stroke-cycle engine the exhaust opens very much earlier in order to get any power at all at even 1,200 r.p.m., and much earlier if the speed were to approximate four-stroke-cycle construction. The earlier the exhaust port has to be uncovered the greater the waste, not only of power but of escaping explosive mixture at low speed. Answering the stereotyped inquiry as to why so many motor boats are successfully powered with two-stroke-cycle engines, we have to say that owing to their low engine speed, low rated power, and designed to run always at the same maximum power developing speed, heavy fuel consumption at normal running is not so noticeable as it would be were variable speeds necessary, as in a motor car.

1676 **As to the Number of Cylinders.**

From P. B. Hughes, Vermont.—1.—Which should give the more power; a four-cylinder engine 4-inch bore and 5-inch stroke or a six-cylinder 3½-inch bore and 4½-inch stroke? 2.—Which would make the best hill climber? 3.—What ought the fuel consumption be in each case, how many miles to the gallon?

Reply.—1.—The piston displacement of the four-cylinder would be 1,005.31+ cu. in., while that of the six-cylinder would be 808.17+. At the same number of revolutions the four-cylinder should be the more powerful, while at the same piston speed the power should be nearer the same. If the six-cylinder is designed to run at a higher piston speed, as most of them are, it should be more powerful 2.—There are so many other conditions than power to consider that we would not even hazard a guess. 3.—For reasons explained in our reply to the previous query, we could not tell without much more definite information.

1677 **Economy in Fuel.**

From R. O. Sylvester, Pennsylvania.—Why is a six-cylinder engine more economical than a four? I understand that the twin-six is said to be the most economical in fuel.

Reply.—It is fully recognized by automobile engineers that a properly designed four-cylinder engine is more economical in fuel consumption than a six-cylinder of the same developed horsepower at the same speed. Adding to the number of cylinders does not make for fuel economy, but for greater speed, flexibility—good pulling power at lower speed than possible in four-cylinder design and construction—and at the expense of heavier fuel consumption. And while on this subject it might be well to add that the fuel consumption per horsepower delivered will be

Digitized by Google

very much higher as the engine speed is reduced. From this it should not be inferred that it would take more fuel to drive a car at half speed over a certain distance, but it would take more than one half as much fuel.

1678 ... His Car Stops.

From F. E. Kneeland, Iowa.—I have a Marion car and it not only starts hard, but it will then run but a short time when it will stop. The carburetor must then be primed again before it will start. Will you tell me something about setting the fuel nozzle of the carburetor? I am afraid I don't understand it.

Reply.—Inexperienced car owners have trouble with the carburetor, and a very common one is that

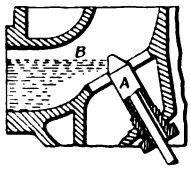

Fig. 1.

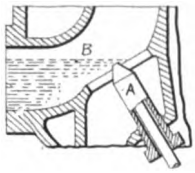

Fig. 2.

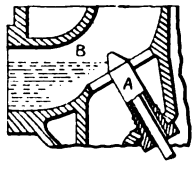

Fig. 3.

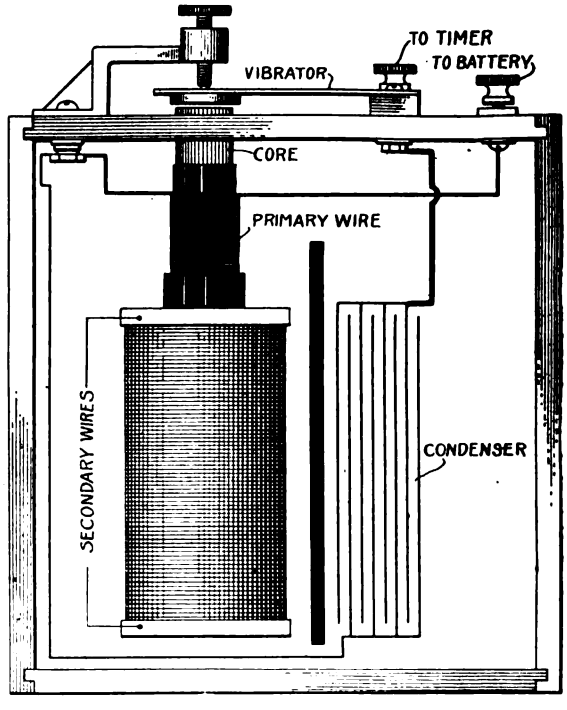
of the jet nozzle, so that the fuel level, as fixed by the float, does not result in the proper flowing of fuel into the vaporizing chamber. Drivers who have trouble with this are frequently puzzled by it, because they assume that the carburetor is properly adjusted before leaving the factory. If spray nozzle A, shown in Figs. 1, 2 and 3, has been lowered, the engine will not get enough fuel at slow speeds and on hills. By raising this slightly, the engine will be able to suck up more fuel. In making this change be careful not to lower the nozzle too much at once, as the effect then is just as bad, the carburetor flooding at the slightest provocation. A better way is to lower the nozzle a very slight amount. Try this level out and when you are satisfied that it is not right, alter the level once more. The experience that you will get during the process will be worth all the time taken up in the series of successive adjustments. In referring to the illustration, Fig. 1 shows the correct location of nozzle, A, Fig. 2 shows the nozzle too low. This will cause the engine to flood. Fig. 3 shows the nozzle too high. Located at this height, the engine will starve. At B, is shown the level of the gasoline. Better send to the manufacturer of your carburetor for a book of instructions.

1679 **Short Circuits, Starter and Electric Troubles.**



From George E. Wakeman, Indiana.—I noted your answer to L. C. H., Vermont, in the August number. I am in a Buick service department and will say that his quotation from the book of directions should be changed to "remove the wing plug on the right side of the motor and put in one-fourth ounce of oil." This correction was given us by the Buick Co. Also, his short circuit, I think, was in his horn. I have had two instances which were similar. One of them where the horn started to blow and would not stop, and the other like his. I found that an insulation on a bolt inside the horn was punctured, which grounded the circuit. In the first instance the ground was where the current left after forcing through the horn, and in the second, where the current came to the horn. The cracking noise indicates a ground at all times. I do not see how the trouble could be in the timer, unless the resistance unit was shorted out, in which case he would soon have trouble with burned Tungsten breaker points.

If R. E. Ingalls, Washington, will cut the brass strip connecting the large terminal and the small terminal on his Delco Junior starter generator and connect his ammeter to the two terminals, he will get both charge and discharge. The brass strip may be on the inside. If so, he will have to remove the armature to cut it.

I would like to hear from Foresman & Lowe, Indiana, as to how they came out with the electric trouble on the Maxwell specials.

1680 **Motorcycle Ignition.**

From Gustave Berke, Wisconsin.—I should like your advice about a motorcycle which I have been trying to fix up. I am not a professional repairer, having a small shop on my farm. I do a little automobile work. This motorcycle when it came to me was missing badly, so I took out the spark plug and wired the threaded part to the frame of the machine and worked the circuit breaker by hand. It would miss about half the time. I tried other plugs; result the same. I also tested the battery. It gave 18 to 20 amperes with no short circuit. I filed the points on the breaker but all this did no good, so I put on one of the coils of my Ford car and it would spark every time. I told the owner his coil was bad; perhaps the condenser was broken down, but as I am no expert I advised him to take the machine to town and have it examined, which he did. The motor-

Showing Coil and Condenser.

cycle man told him he never heard of a condenser and that coils never broke down. He adjusted the carburetor, but it missed the next day again. The machine is an Excelsior, single belt drive, Schebler carburetor, single spark ignition, three cell battery. Sometimes it runs pretty good and again very bad. Should not the spark plug spark outside of the cylinder when it is connected to wire, the threaded part touching the frame?

Reply.—It seems to us that you have shown good

Digitized by Google

judgment and a proper understanding of the troubles of the motorcycle. The spark plug should certainly give a spark outside the cylinder when connected as you describe. If the motorcycle man you refer to says he never heard of a condenser, and that coils never break down, he certainly shows a lack of knowledge concerning ignition devices. We illustrate herewith a jump spark coil, showing the location of the condenser. An ordinary dry cell, used in automobile work, gives a current of from 20 to 30 amperes. It may be possible that your battery has run down, but there is still greater probability that something may be the matter with the coil. For ignition, after an engine has started to run, the dry cell is a rather poor generator to use, for it becomes exhausted in a short time. If we are not mistaken, most motorcycles now use magentos instead of batteries. Judging from your letter, and what you say you have done, a new battery and coil would put the machine in good running order. Many users of motorcycles do not put the attention they should to straining gasoline before using it. We have found, in several instances, dirt in the gasoline has made motorcycles run badly or intermittently. The gauze strainer in the carburetor becomes choked, or there is some obstruction in the supply pipe, and, of course good carburetion cannot be expected in these cases.

1681 A Creaking Sound.

From G. L. Gardner, Long Island, New York.—Will you kindly tell me how to overcome a very annoying creaking sound which is in the right rear wheel of my car, which is a Cadillac, 1914 model. I have changed the rims (tires) but that doesn't seem to stop the noise.

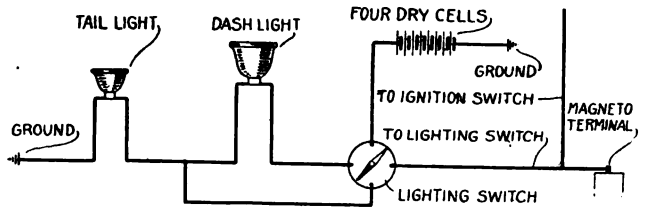
Reply.—Before prescribing the remedy it is first best to locate the cause of the creak, whether in the brakes or axle bearing. Cadillac cars have good, serviceable brakes and when applying them they are liable to squeak pretty loudly. If the trouble is in the brakes, due to dragging of the shoes against the drums, a little adjustment should remedy the difficulty, but if in the axle bearing it means disassembly of the entire axle, and immediate attention at that. It is possible that you have allowed it to remain in this condition so long already that a heavy expense will result.

1682 Ford Car Ignition.

From John A. Brown, Rhode Island.—I would like some advice now about my Ford car, which I bought new last October (1914). I was foolish enough to believe some acquaintances who said the Bosch magneto would make my car run better and more economically and I had a Bosch put on, and it is gear driven. I was not aware when the Bosch was put on that there was no provision for connection of batteries. Now what I would like to know is the best way to make my engine start easier, as it is very much heavier to start than with the Ford system of the K. W. coils and the flywheel magneto. I am told that batteries will be necessary to start on easily. I have a Sanbow mechanical starter on my Ford car and sometimes I pull the starter 8 to 12 times to start the engine, and sometimes I have to prime each cylinder to get started at all, but after the engine is hot it usually starts on the first or second pull of the cord. Now, because my Metz car starts very easily on the Bosch magneto, I can't see how or why the Bosch should be so different on the Ford, if it is properly installed. Please let me know how many and what kind of batteries I had better get to start on. Also if I must have some kind of a coil to go with the kick switch from the batteries to the magneto. The Bosch magnetos may be and probably are all right, but I would be better satisfied if I had the old Ford system back again, because of the starting only, as after starting the Bosch seems to work perfectly satisfactorily.

Now a word about those Metz cars which bob up in your magazine now and then, and claiming to climb hills like a Ford car. I will say if you have any friends who are after a car, say Ford quick for any hard and continuous work.

Reply.—The Bosch Magneto Co. manufacture a good many different models, some like yours not adapted for use with batteries while others of the so-called "dual" type permit the use of either battery or magneto current at will. The flywheel magneto which is standard equipment with all Ford cars, owing to the fact that it necessarily employs a vibrating coil, is not so efficient as an ignition system, either battery or magneto, which gives an absolutely correctly timed single spark, rather than a succession of sparks such as produced by a vibrating coil. We know that many Ford cars are starting easily and giving excellent service and satisfaction to their owners following a change to Bosch ignition, and we feel quite positive that your magneto is not properly installed, or that there is some cause other than suspected for your car not starting as easily as before. Your plug electrodes may not be close enough together, or your make-and-break contacts may not be properly adjusted. It is also possible that the timing may be a little later than will give best results. This is a case where it would be absolutely necessary to view conditions before making a positive diagnosis of the trouble. Of course there is always a possibility that hard starting may not be due to imperfect or faulty ignition. On your Metz car the Bosch magneto has fixed timing, unless adjustable timing has been added to it since it left the maker's hands. You cannot add battery ignition to your present Bosch equipment, nor will Ford design and construction permit two separate and independent systems, battery and magneto. We note what you say about Metz cars. This is not unusual, for we hear Metz owners talk just as extravaganetly of their own cars.



1683 Connecting a Magneto for Wiring.

From W. T. K., Connecticut.—1—I would like information as to how to connect up with a Ford magneto a tail light with a dash light, so the dash will indicate when the tail light is out, and yet have the tail light so it could be lighted with dry cells with dash lights out of connection. What voltage could be used with these lamps so 4 dry cells would work the tail light and how to arrange so it would not burn out with the magneto, or cannot it be done practically at all? 2—I find by disconnecting the secondary wire from the spark plug and placing within ⅛ of an inch of the engine, using 4 dry cells over 20 amperes, I get a flash spark on first turning on the switch of the master vibrator, but there is no spark without bringing the contact nearer the engine though buzzer continues. Does this indicate that something is wrong with my coil? What length of space should the spark jump in the open with 4

Digitized by Google

dry cells and 20 amperes? 3—Have the courts ever passed on the question whether a car standing on the side of the road, not moving (with or without the engine running) is a car being operated on the public highway, and must carry lights as such?

Reply.—1—Wire the tail light and dash tell-tale lamp in series, running a wire from the wire which is connected to the terminal on top the magneto to one terminal of the dash light, another from the other dash light terminal to the tail light, grounding the other tail light terminal to the metal frame. These two lamps should be six-volt. You can use a two-way switch in this circuit. The diagram illustrates the method of wiring. The switch you will note has four contacts. When the circuit from the magneto is completed the two lamps are in series and when the battery circuit is completed only the tail light is in the circuit. You can use a small double throw double pole knife switch if preferred. In this case you would connect the two terminals of the hinge base and use the two pairs of end terminals for completing the two circuits. The circuit

Wiring Diagram.

would then be completed through one knife blade and then through the other, one pair of terminals being used for magneto and the other for battery. 2—It is much safer to try out coils, etc., by means of a spark plug, than by holding the end of a wire at a distance from the engine. It is this curiosity to see how far a spark will jump, which ruins probably 90 per cent. of all spark coils. If the plug gap is too wide you probably know from experience that ignition will not be regular. Just consider what the result would be with plug gaps ⅛ inch wide. You should not expect what you know to be impossible. 3—A car standing at the curb must display a red tail light only. If the engine is running it must show at least one white head or side light, provided only it is one hour past sundown or one hour before sunrise. Plenty decisions back this contention.

1684 Ignition Trouble.

From J. F. R., Indiana.—1—I am having some trouble with my magneto, which is a Remy on an Overland car, of 1911 model. I crank and start the motor on the battery very readily, but if I advance the spark more than 1/3 the quadrant, the motor will stop, unless I run it long enough to warm the motor up good. Then when out on the road I can gradually work the spark up to the highest point O. K. I think the trouble is probably in the platinum points. I don't know much about the mechanism or wiring of the magneto, but find considerable oil around and over the magneto at times, when I wipe it off. Also on the distributing wires from the magneto to the spark plugs, and on one of the distributing wires, just where it passes over the head of the cylinder, I find an exudation of melted rubber, oozing out and dropping down on the cylinder head, which is probably ½ an inch distant. Is this causing any trouble? I have shown this to several garagemen but none of them considered it serious enough to replace this distributor, or recommend a new one put on. 2—The car smokes considerably when the motor is running idle, and just upon starting out for the first half mile or so. I always fill the crank case till the pet cocks drip a little, using Polarine, medium, and sometimes Peerless, medium, but it sometimes carbonizes the cylinders quite badly at times, although I have only had the carbon removed four times from the cylinders and valves, and the car has run 8,000 miles. 3—What brands of oil do you consider give the least carbon trouble and what weight or grade is best for a car that has run so long as this? Would the heavy be all right for summer and winter running? 4—Feeling that my worst trouble is in the platinum points, will you please describe in full detail the Remy magneto of the 1911 make—just how to dissemble and clean the oil and dirt from the inner side and also how to replace new platinum points, and how many points or platinum springs there are to replace with new ones.

Reply.—1—This type of magneto is of the induction type, the windings themselves being stationary and the alternations occurring twice as often during a complete rotation of the rotor as are produced in models using wire around armatures. We believe you should send the magneto to the nearest service station of the Remy Electric Co. for overhaul and probably remagnetization of the partly demagnetized magnets. The manufacturers will probably be able to furnish you with a leather cover which will protect it from the flying oil which a motor five years old is more likely to throw than would one of later design and construction. The dropping of melted insulation could not cause the trouble you are experiencing. 2—Smoking is to be expected from a car which has been run as many seasons as has this one. You will probably only be able to remedy this by regrinding the cylinders and fitting new pistons and rings. Possibly a thicker oil might help a little. 3—We, for well recognized reasons, could not recommend any brands of oil. Old motors seem to give best results with heavy oil in hot and medium in cold weather. 4—Our reply to your query No. 1 should be sufficient reply to this one. There are so very few motors at present using 1911 Remy magnetos that such a description of a very old type of ignition device could hardly interest even a small portion of our readers. The manufacturers, provided they have descriptive advertising matter on hand, would no doubt be glad to send it to you for the asking. We would have to send to them for it in order to reproduce it in these columns.

1685 Engine Information.

From W. J. Tremaine, Ohio.—Will you please explain through the Automobile Dealer and Repairer (1) wherein a high and low speed gasoline engine differs. I have a motor built by the Ferro Machine and Foundry Company, L shape and 4 cylinder 3½ inch bore, 5 inch stroke, ⅝ inch offset crank, valves 1¾ inch in diameter. 2—Is this a high or low speed motor? 3—About what would be the maximum speed of this motor? 4—What horsepower should it develop at that speed? 5—What compression in pounds should each cylinder have? 6—Would you consider this engine large enough for a roadster weighing 2,600 without passengers?

Digitized by Google

Reply.—1—A high speed engine is designed with greater care in the matter of the weight and balance of the reciprocating parts, pistons, rings, wrist pins and connecting rods, as well as valve area, lift, timing, etc. 2—High speed. 3—Probably greatest horsepower would be reached at from 2,000 to 2,500 r. p. m. The manufacturers should be better qualified to tell you at what speed maximum horsepower could be expected. 4—Probably 30 to 40 h. p. We believe the manufacturers are prepared to guarantee the horsepower. 5—Probably about 75 pounds gauge. 6—It should be if geared sufficiently high.

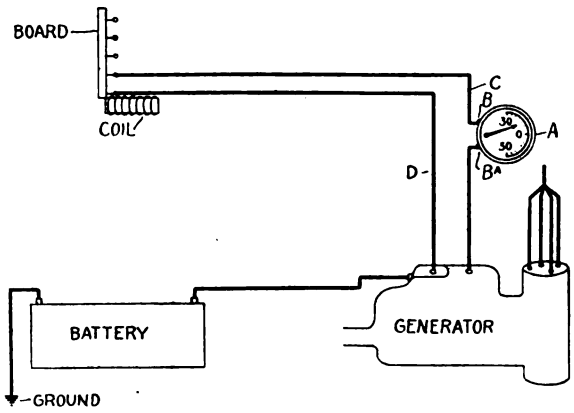
1686 **The Engine Misses.**

From F. C. Bauer, Ohio.—I have a 1912 Little car in my shop for repair. The car has been to three other garages without success. The engine skips and it has done that for the last year and a half. I installed a new high tension magneto, K. W., model J, and tried the engine out but it still skipped just the same. I tried all manner of adjustments on the carburetor. The magneto is timed all right too, but no results. Then I installed model L 2 Rayfield carburetor, with hot air stove, and tried all manner of adjustments but without success. Will you give me some light on the matter that will solve the difficulty.

Reply.—You have proven to our complete satisfaction and probably to your own that the fault is not in the ignition, and probably not in in the carburetor. If your pistons, rings and cylinders are in proper condition, and your valve stem guides are not so badly worn that air leaks at these points are not present, your engine should run without missing explosions. You must remember that the engine is nearly four years old and a good many motor car engines of this age are of little real use except they are thoroughly overhauled and worn parts renewed.

1687 **Carbon Cleaning and Piston Rings.**

From F. Conklin, New Jersey.—My car seems to have lost power. 1—Which is the most effective method of cleaning cylinders of carbon? 2—Is oxy-acetylene good, or which method can you recommend? 3—Also, which piston rings give the best satisfaction?



Reply.—1—Burning with oxygen is probably the most popular method at present in use. It should be done by one who really knows how. 2—Oxy-acetylene should not be used. 3—Those piston rings give the best satisfaction which permit the least loss of compression and which cause the least loss of power from friction. Manufacturers of motor car engines are not all agreed as to the best type, model or pattern. We are frank to tell you that we ourselves do not know. It would be poor policy for us to express any preference for any motor car, part or accessory, or to in any way or manner seek to influence the use or sale of any such particular device or improvement when there may be others equally as good and equally entitled to favor.

Good But Others Pass It.

From George S. Boucher, Virginia.—I notice an article in your June issue from M. A. Foster, of Arizona, concerning the hill climbing qualities of the Ford car. Also his statement, that the larger and heavier cars cannot climb with the Ford. If this means only in Arizona, I have no comment whatever to make, but this certainly will not apply to the mountains of Maryland, Pennsylvania, West Virginia and Virginia. I really feel as though I am lowering the standard of some of the larger cars, in comparing them with the Ford. I am aware of the fact that Mr. Foster can pass some cars on hills, while there are many others that can very easily pass him. I am the owner and driver of a car, which, however, is not a "Metz," which I have driven 8,000 miles, and the only Ford cars that have ever passed me were going in the opposite direction, and on a recent trip between Baltimore, Md., and Uniontown, Pa., and return, I passed a great number of Ford cars. While these hills are not 20 per cent., some of them are steep and very long, and I passed dozens of Ford cars, grinding up these hills on low gears, while I was going at my leisure, from 20 to 30 miles per hour, and my six-cylinder motor was playing a tune that had the "Sextette from Lucia" beat to a frazzle. The Ford car is absolutely all right in its place, which necessarily means behind the modern six-cylinder valve in the head-motor, and, on the square, Mr. Foster, you are not "motor wise," if you are not aware of this fact.

For R. E. Ingalls, Washington.

From J. N. Bagley, Nebraska.—As Mr. Ingalls is having trouble with the ammeter burning up when

Wiring Diagram.

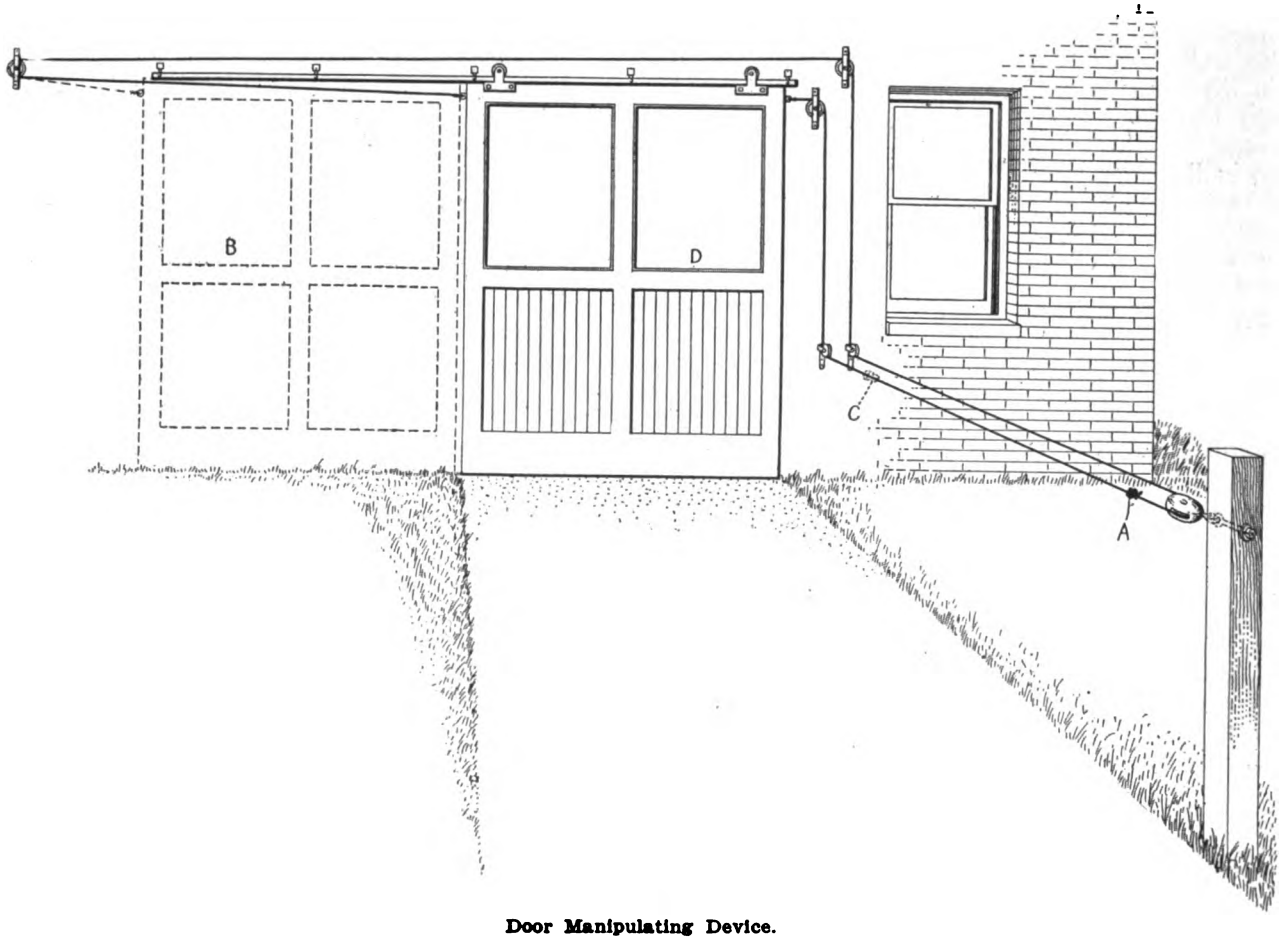
the starter is used on his car, I will try and make plain the method of installing the ammeter so that it will not burn up or be affected by the excessive amperage of the battery. In the drawing we have the generator wired to the battery, and also the wire leading to the board from the generator. Mr. Ingalls has evidently connected the instrument into the wrong line, or line D, as it were, for in this instance when the starter switch was closed, the entire output of the battery would flow through it. Now by placing it in line C, as shown at A, it will only show the amperes given off by the generator and the amperes consumed by the lights, etc., when in use. If after installing the instrument it should show charge when it should discharge it is an indication that the wire connected at B should be taken to BA and vice versa.

Clutches and Coils.

From E. H. Metcalf, New Hampshire.—In inquiry No. 1638, concerning the Flanders 20, section 2 concerns the clutch grabbing. This trouble has been mentioned before in the department, but has not been fully explained. The gradual engagement in this car is secured by a piece of rubber tube put around the clutch under the leather. The ends of it

Digitized by Google

are held by being passed through holes where they can be seen between the arms of the clutch spider. When the rubber has lost its elasticity, the clutch grabs. If Mr. Pierce wants to fix it, he will have to remove his clutch facing, and put in a new piece of tube. The facing can be used again, although after treating long enough with machine oil, it would not be worth while.



While on the subject of Mr. Pierce's troubles, I would offer a guess that his intuition as to the trouble being in the magneto is wrong. With Splitdorf ignition the trouble is usually in the coil. As Mr. Pierce apparently likes to tighten wires when the ignition gives out, it is just possible he may have twisted off a wire to one of the binding posts inside of the box, so that it gives an intermittent contact. I had one like that which gave the same symptoms. The jar of throwing the switch or rapping the coil would often start it. Buy another coil and don't feel obliged to get one made by the same people who made the magneto.

Opens and Shuts the Door.

From N. G. Near, New York.—Most automobile drivers consider it somewhat of a nuisance to have to jump out of the car every time they are leaving the garage for the mere purpose of closing the door. And it is just as vexing to be compelled to get out and do the same thing on the return from a long, dusty trip that has tired one to near exhaustion.

A Connecticut farmer has arranged a scheme for opening and closing his door without getting out of his car. The arrangement is shown in the sketch herewith. It is very simple. He catches hold of a knot, A, in the rope (shown in the sketch) while going in and the door opens as at B. On the way out he catches hold of the same knot, shown in dotted lines, C, and pulls the door shut as at D. This, of course, is done at a low speed, although it is never necessary to stop the car.

A method of this kind is particularly interesting for those who own their own sheds and who do not have to lock and unlock the door every time the car is taken out.

Door Manipulating Device.

Jacking Up Tires.

The Palmer (England) Tire Co.—There is no material advantage to be obtained by jacking all four wheels clear of the ground when a car is merely used during the week-ends. The object of jacking up the wheels when a car is to be laid up for several months is not so much to relieve the tires from local strains at the points where they would be in contact with the ground, as to guard against the almost invariable occurrence of one or more of the tires becoming entirely deflated during such a period. In such a contingency the tires are certain to sustain damage through being pinched between the rims and the ground. If the pressure in the tire is maintained during the whole time the car is idle, we do not consider the tires would suffer in any way. The pressure exerted on the tread of the tire at the point of contact with the ground is not considered sufficient to have any detrimental effect, neither does the slight flexing of the walls, notwithstanding that the balance of the stresses is necessarily somewhat interfered with—by comparison with the stresses set

Digitized by Google

up in a tire fully inflated but supporting no weight. It is obviously much safer, and, in the majority of cases, more simple, to jack up the wheels rather than be bothered with the periodical inflation, of tires. We always recommend jacking or supporting the wheels clear of the ground when a car is going to be laid up for a period extending over a month. The week-end motorist will do more to prolong the life of his tires by seeing that they are properly inflated each time the car is put into service than by jacking the wheels when re-garaging it.

The Roads of New Hampshire.

From R., New York.—Some years ago the writer had occasion to criticize somewhat severely the roads of New Hampshire. He stated that his experience had been that New Hampshire enjoyed the distinction of having the worst roads in the United States.

Recently I had occasion to travel 150 miles or more over New Hampshire roads and can say that the improvement has been very marked. From Ashland, N. H., through Plymouth and the Franconia Notch, up to the White Mountains, the roads leave very little to be desired. From the White Mountains down to the Crawford Notch they are equally good for a portion of the way, and are being rapidly repaired and rebuilt where not already reconstructed. It is a pleasure to observe, too, that somebody of intelligence seems to have laid out these roads, to have constructed them, and to be in charge of them.

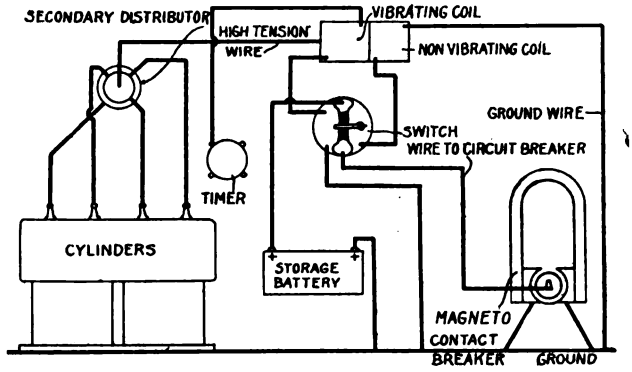
A dirt road, made of the proper material, probably of fine gravel and a little clay, makes a better and more lasting road than macadam.

One of the faults that existed some years ago when macadam roads were being built all over the country was that they were almost universally neglected, until they were worn out and had to be rebuilt.

New Hampshire is taking care of its roads. I noticed evidence of that everywhere. Little piles of gravel are deposited at intervals along the main roads, and apparently it is somebody's business to see that the ruts and holes are filled up as fast as they develop. Of course this is the proper plan to pursue everywhere.

Some time or other the State and local authorities will wake up to the fact that it is cheaper by far to keep a road in repair after it has been built than it is to neglect it and then have to rebuild it every few years.

I am glad to say that I can honestly take off my hat now to the principal roads of New Hampshire. The unimportant highways, of course, have not yet been developed as much as they are likely to be in the future. It has been found, no doubt, in New Hampshire, as it has elsewhere, that good roads bring business. The main road running from Nashua up to the White Mountains has been extensively traveled this summer by automobile tourists.



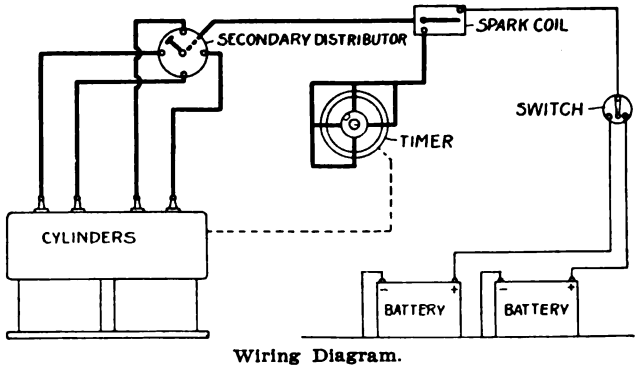
Ever Hear of the Motor Ear?

Thousands of persons are gradually and insidiously becoming deaf with a lessening of efficiency and of mental activity that may have the most serious consequences, says Dr. D. Harold Walker, of Boston, in a paper in the current Journal of the American Medical Association. Another doctor says: "Motoring has become so general that a 'motor ear' is of common occurrence. This condition is caused by the abnormal speed through the air and from the irritation of dust. The use of a little simple oil in the nose before going out and a plain saline wash after returning is good."

The automobile has been accused of about every evil under the sun, but this is the first time we have ever heard it charged with the responsibility of making one deaf. Perhaps some of our physician readers may know whether or not this charge has much basis of fact.

Method of Connecting Magneto in Short Circuit.

The diagram shown in the illustration is for connecting a magneto for short circuit when using bat-



Wiring Diagram.

teries, as when running a magneto on an open circuit it demagnetizes very rapidly. For this reason the wiring should be as shown, when another source of current is used. A magneto gives out current the strength of which is dependent upon its speed of rotation. At high speed it would give a current altogether too strong for a vibrating spark coil and the vibrator would stick on the core.

Wiring Four Cylinders With One Spark Coil.

The illustration shown gives a simple method of how a four-cylinder engine can be wired up, using

Wiring Diagram.

only one spark coil, by having a secondary distributor. This method of wiring has its advantages, some of which are synchronous ignition, reducing the number of electrical connections, and only one coil to adjust.

Before taking the car out of the garage inspect the tires carefully, and if tread cuts need repairs, put on the spare tire in place of the injured one while repairs are being made.

Mr. R. Hill, Matlock House, Devonport, Auckland, New Zealand, is our accredited representative in Australia and New Zealand for obtaining new subscriptions.

WHAT THE AUTOMOBILE DOES.

June 30, 1915, was the end of an automobile year as far as statistics are concerned, and during the previous twelve months automobiles to the value of nearly $525,000,000 were produced and sold. It is safe to say that accessories to about the extent of $100,000,000 in addition must have been disposed of, for these apply to all of the 2,000,000 cars before in use in the country as well as to the 665,826 sold during the year. If we add to this $50,000,000 as a fair expense for up-keep, we have one of the biggest industries of the entire country, involving the use of something like $700,000,000.

"And what has become of the money?" is asked. Why, most of it has filtered down through millions of fingers into homes of toil, and from thence back higher up until it will again reach the hands of the capitalist who will soon be looking for a chance to invest it, and thus the operation of diffusion and a recurring concentration will be repeated. For that is business and industry.

But suppose this automobile business—which the short-sighted claim is an extravagance and a menace to prosperity—had not existed? How would this immense capital and energy have otherwise been employed? "In producing something more useful," we hear some one say. Well, what more useful?

Mention a single thing in the line of necessities or luxuries that cannot now be easily procured and at a fair price, provided the would-be purchaser has the means to purchase it.

Let it not be overlooked that the need of business and industry to-day is not producers but consumers, and that the automobile business has increased the consuming power of thousands where it has not increased the producing power of tens.

During the past ten years the automobile has been the salvation of business and industry. When it finally becomes fully developed and supply is required for replacements only, some other great industry must arise to give investment to capital and employment to labor or dull times will be a reality and not a false claim.

SECOND-HAND CAR PRICES.

It is singular that high priced cars are offered at a greater per cent. of reduction in price when second hand than low priced ones. The reverse should be the case. A car that sells for five or six hundred dollars deteriorates faster by use than one that sells for two thousand dollars or more.

For illustration, at a garage visited by the writer not long ago, where a number of second-hand cars were on sale, a 1914 Ford touring car with no self-starting and lighting system was priced at $285 while a 1914 touring Buick with self-starting and lighting system was offered at $500. Allowing that each had seen about an equal amount of service the Buick was a far better bargain.

In another instance a 1915 Chevrolet touring car was valued at $640, while a 1915 Oldsmobile touring car was priced at $800. Allowing that each was in about the same condition, the Oldsmobile was the cheaper by some hundreds of dollars.

HORSES IN CITIES.

An ordinance which will remove all horse-drawn vehicles from one of its principal streets is being considered in St. Louis, Mo. If the ordinance is passed it will be watched with interest by other cities.

In any event, a mandate of this kind should give time for owners of horse-drawn vehicles to get rid of their teams and purchase automobiles or it is liable to work considerable hardship.

It is safe to assume that it will not be many years before there will be no horses whatever in cities, although the change will come gradually. In the case of express companies and department stores which now use large numbers of horse vehicles, it will be necessary to get rid of them by degrees, either by sale or by wearing them out to uselessness. As for horses, the demand has not been so great for many years, but this is owing to the European war which has destroyed hundreds of thousands of fine animals. If the war should suddenly end the army horses now in the field would be turned back to farm or other business uses, and this would quite likely congest the market for a time and make sales more difficult.

At any rate, it will be a blessing to both man and horse when horses are no longer used in cities. The sooner that time comes the better.

THE PROPER SPEED.

The claim made that a car two years old should not be driven at a greater speed than 30 miles an hour admits of qualifications. It depends upon the road, the car itself and how it has previously been used, and more upon these considerations than upon the broad statement itself. It is true that materials "get tired," as is shown in the crystallization of steel but they do not crystallize from a two year usage. If a car finally breaks down after but two years' use

Digitized by Google

it is more likely to be due to some imperfection in the material or construction in the first place.

But except in case of imperative necessity, why drive either a new car or an old one more than 30 miles an hour? Twice that speed is as fast as railway trains are speeded, and yet these are driven on private roads, with steel tracks and flanged wheels that are unlikely to leave them. The drivers or engineers are familiar with every foot of the way, and in case of a curve of the track it is graded so that overturning is impossible.

Although not every automobile accident is due to driving at high speed, no accident ever occurred where the speed was not too high for that place and that occasion.

A RARE GIFT.

Joaquin Miller was right when he said of the rich man lying in his coffin, "and all he held in his cold dead hand was what he gave away." Posthumous benevolence of those who when alive would part with nothing is of no great credit to them, although we would not go as far as Mr. Carnegie and say that a man who dies rich dies disgraced. Indeed, benevolent as he undoubtedly is, Mr. Carnegie is likely to refute his own assertion, for he will not by any means die disgraced even though he is likely to die rich.

But when a man of forty years, in good health, shows such appreciation of his fellow-workers that he makes them a present of $100,000, it is enough to make one "sit up and take notice." This is what P. W. Litchfield, factory manager of the Goodyear Tire and Rubber Company has done. He has been manager of the Goodyear factory for fifteen years, and by way of celebrating this event, and to show their appreciation of him, his fellow workmen recently gave him a dinner. And he, to show his appreciation of his fellow workmen, presented them with a check for $100,000, as a general welfare fund.

In giving this sum he said: "This fund is given with the idea of sharing with my co-workers a part of the savings which I feel they have shared in producing. Its continued existence in considerable amount should tend to unite Goodyear workers, and give them a sense of responsibility, educating them in business methods, promoting thrift and saving, developing loyalty, efficiency and co-operation, and cause them to feel that they have something saved up for their use in order to tide them over the emergency of a 'rainy day.'"

A GREAT REPROACH.

The greatest reproach upon twentieth century civilization is neither inhumanity nor selfishness, nor wickedness of any form, nor crime of any form, nor indolence, nor ignorance. There are less of any of these to-day than at any other period of the world's history.

By far the greatest reproach upon twentieth century civilization is the need of so much charity and benevolence. This is expressed in the so-called "minimum wage" laws, in the almost innumerable things that poor people now have done for them by the State—in free hospitals, free school text books, free dentists for school children, free old folk's homes, free pensions, free baths, free places of amusement, free churches and free what-nots of never ending and fast increasing numbers.

Of course, you understand us. We say the *need* of so much benevolence is the reproach, and not the benevolence itself. Having the need of it, it is to our highest praise that it is not withheld. But the need existing, and being generously supplied, it is bound to increase and grow broader and deeper, like a noxious weed or a contagious disease. For the end is not yet, and no one can foresee the end.

Why not more justice and thus have less need of benevolence? This is an automobile periodical; we do not intend to get into the domain of political economy, but if the foregoing leads some one to indulge in the luxury of independent thinking it will have answered its purpose.

ROAD TAXES.

To make automobile owners bear the brunt of the cost of improved highways when such improvements add more than their cost to adjoining land or farm values, is unfair.

Most of the abandoned farms one may see here in the East are the result of their being cut off from the markets and their isolation from the social and other amenities of civilization. Good highways are of more value to the farmer than to any one else, and they are of more value whether he wants to sell his farm or till it and take its products to the market with some degree of economy.

It is true that automobiles injure the roads if driven rapidly; and on the other hand, if driven slowly they are a positive benefit to them, pressing the roads down much like a steam roller. In fact, the effect of automobile driving depends so much upon speed that if absolute justice were practical or possible, the slow driver might well be rewarded and the fast one punished.

When all their varied ramifications are considered, good roads benefit the entire community, residents and non-residents, property owners and wage workers. And the entire community should pay for them.

We know of no better theory of taxation than that laid down by Adam Smith 150 years ago or such a matter. It was that all individuals should contribute to the expenses of government as nearly as possible in proportion to their respective abilities. It is true, that in this way, some will get greater benefits than others for a given amount of taxation. but the principle itself is the only practical one that will work out satisfactorily.

A COMPARISON.

Automobiles are like human beings; those which make the most noise do the least and the poorest work. And the quality of an automobile can be determined by the character of the noise it makes while running, just as the quality of a man can be determined by the character of the noise he makes while working.

The automobile that can be depended upon to take you there and back, runs quietly and with a purr or a hum rather than a rattle and a bang. So it is with the man.

The well made and efficient automobile needs little attention; neither does the man.

And finally, the value and service of an automobile should depend upon its cost, but this is not invariably the case; neither is it so with the man.

That venerable critic, William Winter, says: "Half of the activity commonly called work, consists of parade and pother. The actual work of the world is done silently, by the minority, and usually it does

Digitized by Google

not occupy all the time or exhaust all the strength." The fact is, one can make hard work easy or easy work hard, but the best test of efficiency is lack of "fuss and feathers." The efficient automobile passes on the road so silently and easily that one is scarcely aware of its presence, and so it is with the efficient man.

THAT POISONOUS GAS.

The instructive article by Dr. E. H. Van Patten, of Washington, in relation to the danger of poisonous gas in closed garages or other rooms, needs no amplification, and mention is made of it here merely to call our readers' attention to it as something that should be carefully noted.

The only way to ensure safety from the effect of this poison is to see that the garage is invariably well ventilated. Probably this poisonous carbon dioxide is slightly heavier than air, and if so, there should be free circulation low down in the room if possible.

In any event, now that we know the nature as well as the cause of the poison, a little care will avert the effects or recurrence of it, and Dr. Van Patten has performed a real service to our readers by his timely article.

NOT BECAUSE IT IS "CLASS."

Some denounce the taxing of automobiles on the ground that it is "class legislation." But the fact that it is class legislation does not make it unjust. Class legislation is either good or bad according to its effect upon the public welfare, just as all other legislation is either good or bad according to that standard.

Class legislation that promotes the public welfare is good; class legislation that does not promote the public welfare is bad. The simple fact that it affects certain individuals and not others is of no consequence one way or another. But the fact that it achieves what all laws should achieve, the advancement of the public weal, is of supreme importance. The idea of opposing a law because it bears heavier on one individual than another is no longer defensible; the public weal is the goal of all legislation and whether it hits a few individuals only or many is of no consequence compared to the larger and correct view.

The singling out of automobiles for taxation any more than any other vehicles or property, is unjust simply because it tends to hinder and obstruct the public welfare. There is no better form of taxation than to simply tax all kinds of property alike.

LET IT ALONE.

If your car runs properly and quietly, do not attempt to improve it unless you are an expert. Frequently, readers come to us with statements of how they have tampered with their car in attempts to improve it, and possibly when just out of the factory. Invariably, they have come to grief and wish they had not meddled with it.

It is a rash thing to attempt to improve upon the manufacturer's design and construction which are usually the result of long study and experiment. The car of to-day is really the result of the experience of thousands of car owners and designers, and the purchaser may be sure that if there were any way to make it better with slight additional expense, the manufacturer would be the first to adopt it. As in the case of anything else, "let well enough alone."

LESSONS FOR DRIVERS.

Carelessness and Ignorance Responsible for Most Accidents.

Grade Crossing Accident.—Near Medora, Ill., a little girl was killed and her mother injured, when in approaching a grade crossing the mother who was driving failed to see the oncoming train, as the crossing was obscured by an embankment covered with weeds. When she saw the train upon her she quickly turned the steering wheel in an effort to avoid the track, but the machine was struck and the child was killed.

At a Sharp Turn in the Road.—A driver was rammed against the steering wheel and pinioned beneath his machine when it turned twice over near Sabin, Minn., and death soon resulted. Although it is stated that the car was not going at an excessive rate of speed, the party were all in high spirits and intended to be in a higher one in an hour or so.

Warning Remark Confused Driver.—A man was instantly killed near Glenwood, Col., when in crossing a bridge in a car he had just purchased, he lost control of the machine and ran into a post, then plunging to a rocky creek bed below, carrying the occupants with it and pinning them beneath. It is stated that just before the accident the driver was told to be careful of an abrupt bank on the opposite side of the bridge, and it is thought that the remark somewhat flusterated him and caused him to lose control of the car.

Engine Died on Hill.—Six people were injured and buried in a swamp near Elkhart, Wis., when in climbing a steep hill the engine died and the driver was unable to set the brakes so they would hold. The car started down hill, shot over a steep embankment and overturned in a swamp, burying the occupants beneath it.

Failed to Shift Gears.—At San Jose, Cal., a man had his chest crushed when in shifting his gears to make a steep grade he failed to engage the cogs and the machine started backing, going off the road before the driver could set the brakes, and down a precipice.

Grazed Another Machine.—Two young men were killed in an automobile accident at Galion, Ohio, when the car in which they were riding rubbed against another in passing, throwing it out of its course and against a large tree. One of the young fellows was killed instantly and the other died in about twenty minutes.

Bee Causes Wreck.—A bee was responsible for the wreck of a touring car near Allentown, Pa. It appears that a bee lighted on the chauffeur's neck. He brushed it off and it landed on the lap of one of the lady occupants. The driver then gave it a swipe and in doing so lost control of the wheel and the car collided with a bridge abutment. Two of the passengers were cut by broken glass and the car was a wreck.

Caught Between Two Trolley Cars.—In an effort to cross the trolley tracks upon which two cars were traveling in opposite directions, near Waterbury, Conn., an automobile was caught between the cars and crushed. One little boy was fatally injured and his sister and parent badly hurt. They were all

Digitized by Google

taken to a nearby cottage where a doctor took charge of them.

Emergency Brake Failed.—A young man and woman died in a hospital as the result of an accident, near Pinal, Tex., at the foothills of the Pinal Mountains. While ascending a hill the engine died and the emergency brake failed to work. The car rolled down hill, struck a rock and turned over and the man and girl were pinned beneath. Dripping gasoline set the car on fire and they were terribly burned before assistance came.

Street Car Light Causes Collision.—Blinded by the headlights of an approaching car in East Plato Center, Ill., caused a man to miscalculate the distance from the oncoming car and to drive his machine directly in its path. A collision resulted in which he received a broken arm and a badly bruised and cut body.

Brakes Fail on Wet Street.—At Chicago, Ill., two women were instantly killed, when in making a sudden turn the machine swung in front of an approaching trolley car. Both the motorman and the chauffeur saw that a collision was inevitable and applied the brakes, but on account of the wet streets the brakes would not hold. The car struck the automobile throwing it thirty feet onto the sidewalk. The women were both dead when picked up.

Fifty Miles an Hour.—A young man was instantly killed near Urbana, Ill., when with three companions in an automobile, going at the rate of fifty miles an hour, it turned over at the foot of a steep hill. The young man was thrown out and his skull was crushed. The others were not injured.

First Ride Fatal.—The first ride in a new automobile proved a fatal one to a woman in Fairfield, Ind., when the automobile was struck by an express car at a grade crossing. The woman and her son were driving and did not hear the whistle of the car until it was almost upon them. It was too late to apply the brakes so he drove ahead and the automobile was hit in the rear, killing the mother and injuring the son.

Hard of Hearing.—Two old gentlemen were instantly killed at Decatur, Ill., when the automobile they were in was struck by a trolley car. They were hard of hearing and a high hedge made it impossible for them to see the car. The bodies were so badly torn that they could not be recognized.

Too Much Confidence.—A woman was knocked down and dragged twenty-five feet, at South Chicago, Ill., by a driver who after a few instructions felt competent to drive his car himself.

Goat Wrecks Automobile.—A goat was chained to a fence at the roadside near Galeton, Okla., and stood in the middle of the road when the car approached. The car slowed down but not before the chain became entangled in the wheels of the automobile, sending it over an embankment. Two people suffered broken legs and two others were bruised seriously.

Misjudged Nearness of Bank.—Near Colfax, Wash., a man was attempting to pass a team, and although he was driving slowly the car slipped from the road and rolled over and down an embankment 30 feet below. His head and chest over the heart were crushed and he died instantly. The other occupants of the car escaped injury.

SELF STARTERS.

The Subject Concluded with Explanations of Popular Systems and Devices.

BY C. P. SHATTUCK, M. E.

No. 4.

During the past two years the number of automobile manufacturers who have replaced the magneto with the motor-generator having a timer-distributor has steadily increased. As a result makers of lighting and starting equipment have incor-

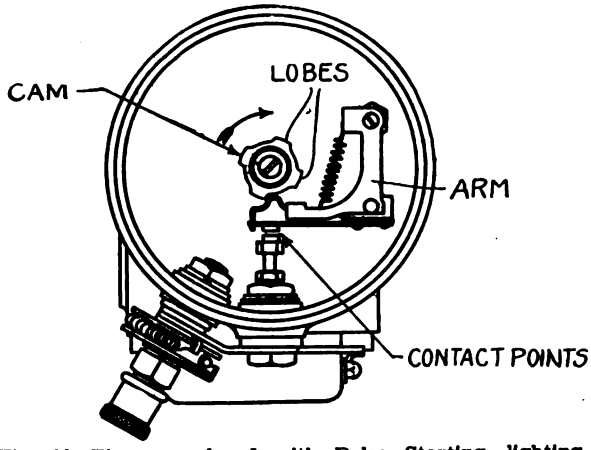

Fig. 32—Timer employed with Delco Starting, lighting and ignition.

porated ignition with their units, relying upon the storage battery charged by the generator or the dynamo itself for supplying electricity. The use of the battery or generator for obtaining current has resurrected the older principle of ignition but in a new form as the timer or interrupter of the primary current is very similar in principle and is held to be as efficient as the perfected magneto.

The Delco system of starting, lighting and ignition, produced by the Dayton Engineering Laboratories Company (the name Delco is obtained by

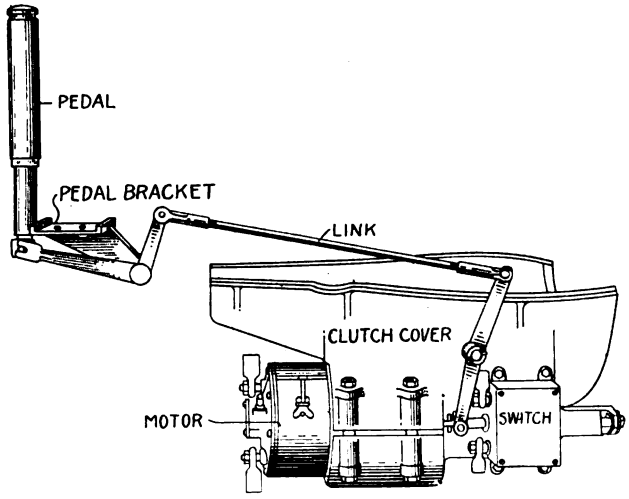

Fig. 33—Illustrating installation of Bijur motor starter on a used car, the Packard.

using the first letter of each word) may be said to be the pioneer system. It was and is to-day a motor generator on which is mounted a timer-distributor and a transformer coil. A sectional view of the unit was shown at Fig. 22 in the July issue, and it will be remembered that the timer and distributor were carried on the front end of the unit, and driven through a set of spiral gears attached to the arma-

Digitized by Google

ture shaft. As the timer-distributor is a component of the starting and lighting system a brief description of its construction and operation will be of interest to those motorists owning cars equipped with it.

The Delco timer, shown at Fig. 32, is directly beneath the distributor which is a cap or head of insulating material carrying one high-tension contact in the center with similar contacts spaced equidistant about the center. A rotor maintains constant communication with the central contact. This rotor also carries a contact button which serves to close the secondary circuit to the spark plug in the proper cylinder. The timer differs from the old fashioned commutator in that it is of the contact or make and break type. It consists of a cam, C, which has as many lobes as there are cylinders of the motor, and a movable arm which is pushed outward by the lobes, the action closing the contacts or establishing the primary circuit. The spark occurs at the instant the contact points break, much in the same manner as the points of the circuit breaker of a magneto, and the low-tension or primary current is intensified by the coil, conducted to the central high-tension contact of the distributor and distributed by the button of the rotor. Generally a set of dry cells is provided for emergency, enabling the motorist to reach home in the event of disorder of the generator.

In the wiring plan of the Bijur motor-generator as installed on the Scripps-Booth car the system provides ignition as well. The cable carries the intensified current from the coil as well as the leads from the distributor to the spark plugs. This system is to be changed, the shunt field lead being carried to the starting switch, the frame of the starting switch being grounded and the construction such that when the switch is turned to the "Off" position, the shunt

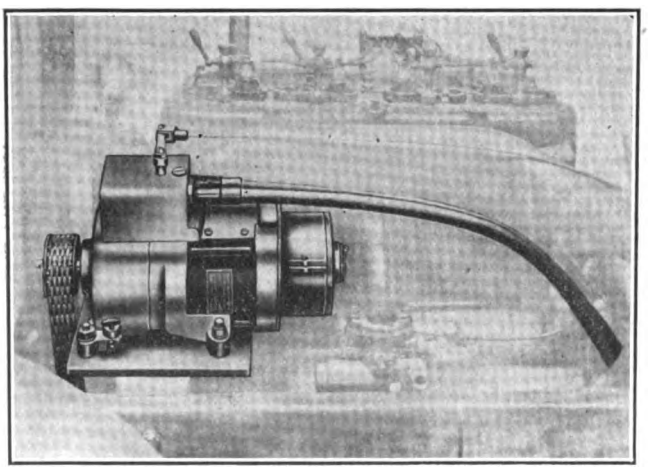

Fig. 34—Application of Jesco Motor Generator to a Continental Motor.

field circuit is opened. The shunt field was fully explained in the first article of the serial.

Motor Starters on Used Cars.

Manufacturers of motor starters disagree as to the practicability of installing a motor starter on the used motor vehicle. The majority hold that it is a manufacturer's problem; that is, the unit must be constructed to meet the requirements of the motor. Other makers hold that the motor starter is adaptable to the used car and in proof of their assertion is the large number of old cars equipped with cranking units.

Those not favoring the installation of a motor starter on the used car take the stand that generally the cost of adapting the unit to the motor involves considerable alteration and expense. And in addition if the system includes separate units, a motor and a generator, the latter being necessary to maintain a battery in a charged condition, the expense will be increased. One prominent maker of starting and lighting equipments states that invariably the motorist will decide upon a system that cannot be fitted to his car without involving considerable ex-

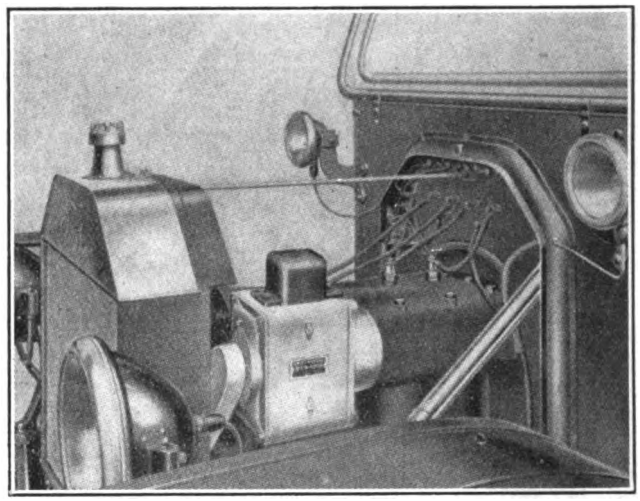

Fig. 35—Gray & Davis System for Ford cars.

pense. The writer knows of several well known makers who always advise an owner of the used car when seeking for information not to attempt to install the system.

This does not apply to a certain number of makes of motor vehicles. A limited number of manufacturers of starting systems have brought out and perfected units that can be installed on certain makes of used cars at a reasonable cost. Among these may be named the Bijur starting system for the model 48, 1912 and 1913 Packard cars. The system is installed by removing the bottom clutch cover, dismounting the clutch, installing a new flywheel and reassembling the clutch. The new flywheel carries a toothed steel ring and a pinion of the motor starter meshes with this large gear. A new clutch cover casting is supplied, and the motor is clamped to the cover by means of bolts as may be noted at Fig. 33, which shows the unit installed. The system includes a switch, linkage, pedal bracket and the starting pedal. A generator or dynamo is necessary and is included with the system.

The most common method of imparting the energy of the motor to the engine and taking the drive for the generator of the motor-generator is by silent chain; that is, when the installation is made on the used vehicle. Fig. 34 illustrates the application of the Jesco motor-generator on a Continental motor. The starter is mounted on the arm of the engine by means of a special bracket and connected to the crankshaft through a silent chain which operates at twice crankshaft speed. These examples are quoted to show that the motor starter can be installed on the used motor vehicle.

Ford Installations.

The contention is further borne out in practice by the successful application and operation of the

Digitized by Google

lighting and starting systems built for the Ford car. It was but logical that the manufacturer of starting and lighting systems should produce an equipment for this car as the demand for a cranking unit has been very large. Among the manufacturers building starters for the Ford are: Gray & Davis, Splitdorf-Apelco, General Electric Company, Westinghouse Electric and Manufacturing Company, The Esterline Company, Hartford Suspension Company, Fisher Electrical Works, Kemco Electric Manufacturing Company, Disco Electric Starter Company and several others.

The Gray & Davis system for the Ford car consists of a motor-generator, six-volt battery, battery box lighting and starting switches, regulator-cutout, chains, sprockets and wiring. As a rule the entire necessary apparatus is supplied. The motor-generator, including the regulator-cutout, is mounted on a specially designed bracket bolted to the crankcase and water connections, permitting of removal of the cylinder head when desired. The generator operates as a shunt wound machine when charging the storage battery and as a compound wound dynamo when supplying electricity for the lamps. The energy of the motor starter is applied through an enclosed silent chain to a sprocket on the crankshaft of the engine. The starting switch is located in the floor board.

The Splitdorf-Apelco starting and lighting system for the Ford, marketed by the Splitdorf Electrical Company, Newark, N. J., differs from the system previously mentioned in that it is a 12-6-volt motor-generator. The storage battery is divided into two individual six-volt cells and these are connected in series by the starting switch, supplying a 12-volt current for operating the motor. Upon releasing the starting switch, which is illustrated at Fig. 37, the cells are connected in parallel and charged as a

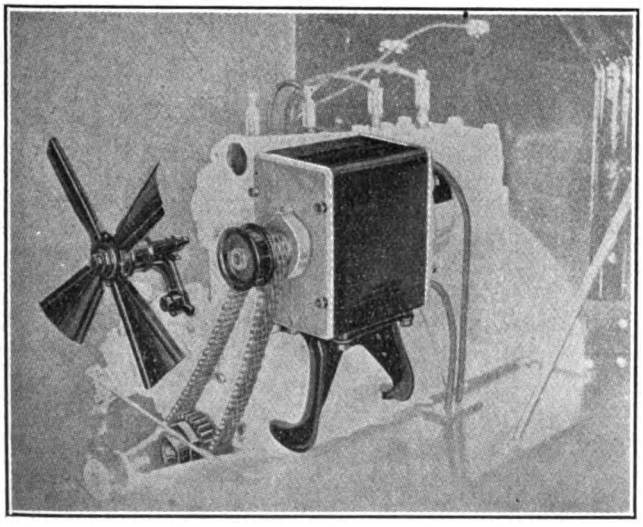

Fig. 36—Splitdorf-Apelco Starting and Lighting System for Ford cars.

six-volt unit. The current supply to the lamps and ignition is a six-volt at all times. The maker states that the use of 12 volts for starting insures sufficient energy to spin the motor in the coldest of weather, makes for economy of current consumption and permits of the use of 6½ or 7-volt standard bulbs.

Energy for starting is imparted through a silent chain to a sprocket on the crankshaft while drive for the dynamo is by a belt. The construction eliminates the necessity for overrunning clutches and for gears, and the armature of the machine has but one set of brushes and but one set of windings. The

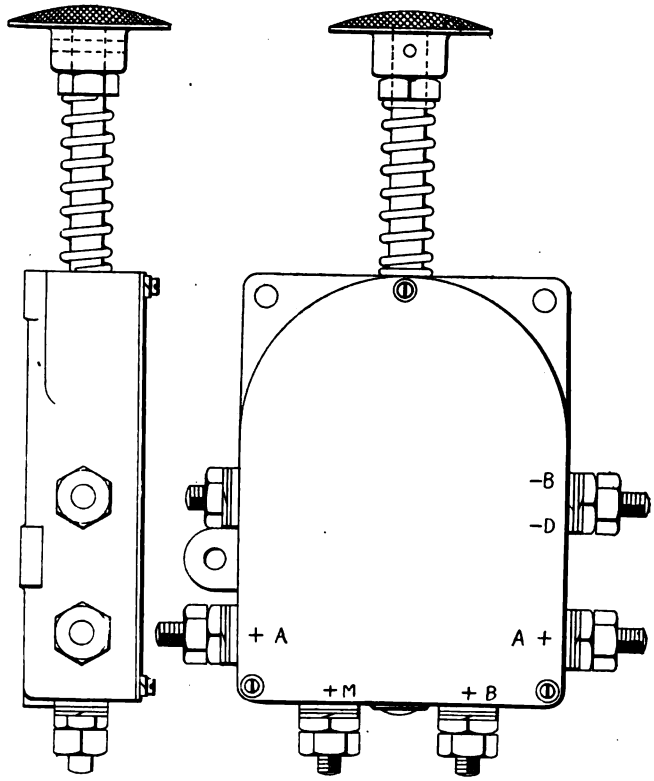

Fig. 37—Splitdorf-Apelco starting switch which connects the cells of battery in a 12-volt circuit when starting.

required reduction between the unit and crankshaft is provided by the sprockets.

Mention should be made of the starting and lighting system marketed by the Kemco Electric Manufacturing Company. This consists of a generator around which is built the fan, the construction replacing the Ford fan. The unit keeps the battery charged for supplying current to the motor starter which is practically of the type made by this company for large cars and which was described in a previous article.

Mention should be made of the heart of the motor starting system, the storage battery. The current supplied by the generator is stored in it and its proper maintenance is an important factor in the successful operation of the starter, particularly in cold weather when the lubricant congeals, the lubricant requiring more energy to overcome the starting torque. Plain and specific instructions are given by every battery maker and these should accompany each car. The instructions as to the use of the hydrometer should be carefully followed.

Car Starts Hard When Hot.

It is not often that a car starts hard when hot. When it does there may be too close an adjustment of the valve tappets when cold, so that when the motor is warm, the valves do not shut tightly. Or the cause may lie in the spark plugs. If these are heavily covered with carbon, the resistance offered by the deposits will increase with their temperature; furthermore, the plugs expand in the heat, which again tends to increase the resistance.

THE KNIGHT OVERLAND.

Brief Description of This New Engine and Chassis.

The new sleeve valve engine for the Willys-Overland car is receiving much attention both in this country and in England. It will be remembered that this magazine was the first to pay any attention whatever to the silent Knight engine, and to endorse it to the extent that it was something likely to be successful. That view has since been fully proven substantiated.

An important feature of the sleeve valve engine as used by the Willys-Overland firm is that it is one of the lightest of this type yet produced, though it is quite powerful, its actual rating of 40 horsepower being obtained at 1,400 revolutions per minute. The compression is 75 pounds to the square inch when cold, this being fairly high. The cylinders are cast in block. It is cooled by the thermo-siphon system. In connection with the cooling system, the separate aluminium head-plate, which covers the top of the cylinder block, and forms part of the water jacket and also the outlet to the radiator, is a notable piece of ingenious construction. This head-plate is screwed down by four large nuts, which, with the aid of a suitable gasket and packing glands make the necessary watertight joints. With this method of construction it is possible to have the water jackets around the cylinders actually communicating direct with the heads of the cylinders, which are, nevertheless, individually detachable, as in the standard type of Knight engine. This renders all external joints unnecessary, while the actual circulation of the cooling water around the plug seat and in the domed head is ideal. Another interesting feature in the cooling system is the fact that the combustion head is so shaped that the water contained in it siphons out automatically when the water in the cooling system is being drained off for any purpose.

With regard to the actual valve mechanism there is nothing unusual, there being the usual two sleeves surrounding the piston, with a ring joint in the combustion head. Similarly the actuating mechanism consists of an eccentric shaft with small connecting rods which are attached to suitable lugs at the base of the sleeves. The rectangular ports are also similar to known practice, extending around part of the circumference of the sleeves, the cylinder slots being correspondingly proportioned. The vertical movement of the sleeves is 1 inch at, of course, half the motor speed, as the silent chain drive from the crankshaft to the eccentric shaft has, naturally, the usual one to two reduction. When the engine is running, say, 900 r. p. m., the sleeves are only traveling at a rate corresponding to the piston speed at 100 r. p. m.

With this design of engine the valve motion is, of course, entirely mechanical, so that it differs from the poppet valve motor in that the valves are bound to close absolutely as they set to close, instead of being dependent on a spring, the temper of which may vary and thus alter conditions. One of the main claims of advantage in the Knight design is based on this fact. No matter what the speed of the engine, a proper mixture can always be obtained, as the opening and closing of the valve ports are always absolutely positive and in complete synchronization relationship with the piston speed. The exhaust begins to open at 40 degrees before the bottom dead center, and closes 5 degrees after the upper center. The intake opens 6½ degrees after the upper dead center, and closes at 45 degrees after the bottom dead center, consequently one gets the benefit of an important desideratum, namely, the maximum duration of full port area. It will be seen that the exhaust valve is open for 225 degrees of the revolution of the half-cycle concerned, and the intake open for 218.5 degrees. The crankshaft is carried on three main bearings, and is, of course, of the conventional type. The exhaust manifold is a separate casting, there being an individual outlet from each cylinder so as to place the minimum of retarding influence in the way of a speedy exit for the gases. The intake manifold is internally cast, and the carburetor is bolted up directly to the engine.

With regard to the question of lubrication, the keynote of the design is simplicity, the method adopted being a combination of force feed and splash. There is a reservoir at the base of the crank chamber from which the oil is drawn. The action of the sleeves is such that when the oil is thrown on to them it is carried up, and distributed to perfection automatically by the continually varying reciprocating action and the suction effect. There are circular grooves cut in the outside of each of the sleeves. At certain intervals there are ⅛ inch diameter holes in the sleeves, so that the oil spray beneath the piston, while affording the gudgeon pin lubrication, may also pass through these small holes and thus assist in the internal lubrication of the outer sleeve. The quantity of oil in circulation is governed by a by-pass, which is operated synchronously with the throttle, the amount of oil supplied always being proportional to the throttle opening. The construction of the pump is such that its entire barrel oscillates while it is pumping. The starting mechanism is much the same as the Overland, as known and sold at present.

In general terms one may say that the rest of the chassis, and also the body construction, follow standard Overland practice as used on their six-cylinder model. The drive is taken through a leather-faced cone clutch with subsidiary springs beneath the leather so as to ensure easy engagement, and then through a three-speed and reverse gear set to the floating rear axle. The tail shaft, which has its universal joint at the front end, is enclosed within a torque tube which is rigidly attached at the rear end to the gearbox, the latter, of course, as in the standard Overland model, being built up in conjunction with the rear axle casing. Three-quarter elliptical springs are used at the rear of the chassis, and these are of the underslung type. Large brake drums are used and both the brakes operate directly on the rear wheels.

There are many evidences of ability in the design of the engine, especially with regard to some of the details, notably, for instance, the attachment of the combustion head cover plate, which is an excellent example of the designer's art. Not only has he obtained the highest possible efficiency in the work in question, but he has also managed to maintain at the same time a simplicity and neatness of construction which are bound to obtain high commendation.

The oil drop and the dirt and dust drawn in through the radiator by the suction of the fan, combine to make a dangerous accumulation of material in the dust pan.

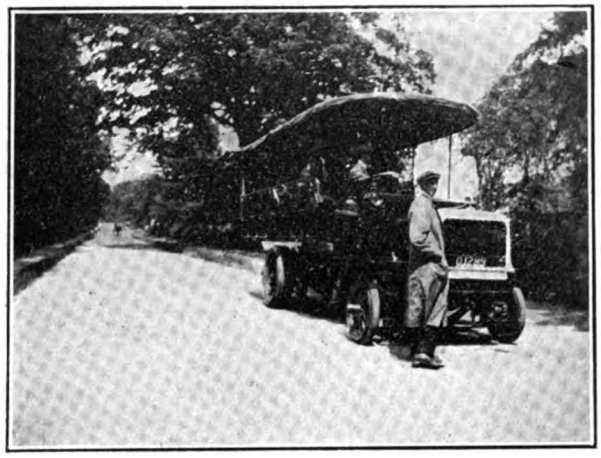
MOTOR COACHING IN ENGLAND.

Vivid Pictures of a Trip Through the Pastoral Shakespeare Country.

From Felix J. Koch, Ohio.—It invariably produces the effect desired. Pretty Mrs. Jack Roosa, returning from a protracted honeymoon, turns to the group of friends gathered to hear all about the journey and remarks, with all the modesty a traveler is presumed to assume:

"Jack and I motored through the Shakespeare country in England, all the way from Leamington to Stratford, stopping off at Warwick and Kenilworth and Guy's Mill, and so on, and to my dying day I never expect to enjoy a more charming trip!"

Whereupon auditors see mental visions of an automobile chartered to the purpose, and remark how lucky was Mrs. Jack Roosa that she could go this wise, instead of being cramped, as were those of the company who had "done" England inside one of the stuffy, old-fashioned stages. Naturally, Mrs. Roosa enjoys this friendly envy of her colleagues, and answers each and all of their questions, omitting only to state that just as she motored through Shakespeare's England, so, that same year, 200,000



The Old Way.

others motored or "coached," as they call it, and this on a huge motor coach, built for it, and crowded every warm day of the year. Or again, Madam Roosa will speak idly of "coaching through England," failing to add that the old-time stage coach has been expelled by the motor and that the kind of stage coach which her auditors may form in their mind is as great a curiosity in England as it would be here at home.

While the lover of the unique inland travel cannot but view with regret the passing of these old English stages, in which countless generations of tourists were borne through the Shakespeare country, or Wales, there is this to the new order of things, that it is certainly far more convenient that one can make several times the speed on uninteresting stretches of country, that one can keep to a schedule, as you can't with a coach-and-four, and that, in the event of a sudden downpour, you can retreat to cover rapidly.

Most travelers board these motor coaches at Kenilworth. The busses start at Leamington, a center of touristry for the Shakespeare country, but they hardly allow one the time at the old castle he desires, so that he who would do his sightseeing thoroughly prefers to board an early train and come to Kenilworth, explore the route to his satisfaction and then connect with the motor-coach when it comes to this place.

Your vehicle, you discover, is a most substan-

The Modern Way.

tially built motor coach, with an aisle down its center, seats for two at right and left, four such to each side. The far rear and the far front seat are built completely across, accommodating one more tourist if need be.

Soon you are bowling through Kenilworth village. The quaint little brick houses, some of them exceedingly small; old St. John's church of stone, with the clock showing 12:10 now; an array of potatoes and carrots, placed by a housewife before her home, pending use; these, and other similar vignettes of village life in England, whirl past you. Meanwhile, you are taking stock of your companions, renewing acquaintance with a tourist you met in the British Museum some weeks past, and are remarking how very flat, very smooth is the road, and how well kept is the walk just beside it.

The full thrill of pleasure that always accompanies motor coaching is already upon you, as you strike into the open country. There, too, these English roads continue smooth as glass, and on a level with the hay fields, and the broad acres of cab-

A Characteristic Inn.

bage or other vegetables or grain that stretch away as far as the eye can see.

Your seat-mate, a motorist from the States, grows enthusiastic at the fine "black asphalt road," as he

Digitized by Google

calls it. Despite the speed at which you are traveling now—well-nigh that of an express train—this man takes snapshots of the fields, of a little brick schoolhouse, and of a wee village of old, thatch-roofed houses, whence the noise of the smith at his anvil seems the only token of life.

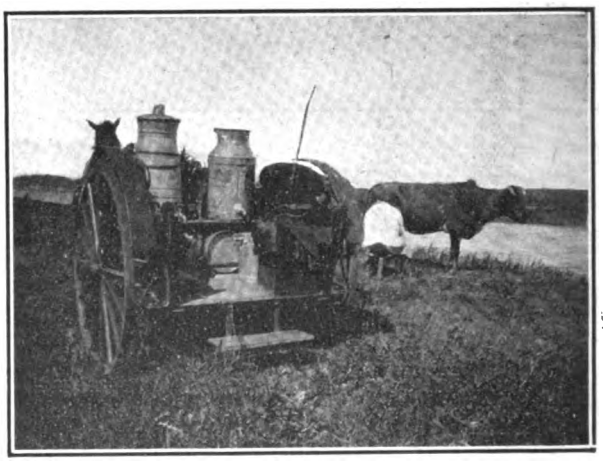
Then your attention is diverted by a side-road, leading off to Coventry. Just as you were relating to your vis-a-vis an article you read years ago, of that place, the turreted steeple comes in view on the right, then some homes, with the bricks set in between the old wooden beams, and then a broad oat field gives way to high hedge of arbor vitae.

A Roadside Restaurant.

You dash through a grove, to emerge on a beet field and then stop a moment to note how the hay is cut here. This is compressed and the neatly trimmed blocks are then set one on another.

Somehow, as you ride, you can't help but think of how much more peaceful, more quiet the scenes when the old horse coach plodded here. Then the flock of chickens, among the trees yonder, would not have fled from your path as they do, the lodge in the hedges would not have gone by so quickly, and the oats would have sent a soft rustle to your ears.

But you'd be nowhere nearly so far in such little time. Already they are stopping at Guy's mill; five minutes here to let you see the oldest working mill in all England. Tourists from all the coaches are clambering down, walking down a road between walls overhung by old cedars; cutting through a little vegetable garden, then coming to this ancient mill. Wonderfully interesting that, but a story for other pages. It is these little halts here and there that make the trip so attractive. There is time for them, as there could not be with the horse coach that would bring its travelers in with any reasonable sort of time.



Back aboard, the coach returns to the main road, and on, on you speed. At one side there is an open area of lawn, the width of an average city street—this flanked by forest primeval—which, in its turn, leads off to a house, one of the old English manors, no doubt. Ever lovelier and lovelier becomes this highway! You do not wonder any longer that returning travelers enthuse at the coaching through the Shakespeare country. And it's cheap, very cheap. Just as the camera fiend is snapping the iron fences put round the trees in the meadows to protect them, the fares are taken. Only $1.20 for a ride covering the best part of the day. Again and again you comment on the road, without a speck of dust on it. You pass over a river, on between hedges, and along walks bordered by walls, ivy covered. A postman is busy here, a huge hat box on his arm, showing the use to which parcel post is sometimes put here. Then, a turn, and you are in Warwick village. Once more you've the little homes of brick, trimmed with stone, the neat shops, the buildings coated with the smooth, yellow plaster. Groceries, ale shops, coal dealers' establishments are all here. Then you slow up at the huge stone gate, gray with age, that marks the foot of old Warwick Castle. Queer old buildings, white and black, in turrets of stone, begin to take the notice also. Out before the Parrot Tea Rooms a huge green parrot hangs, and at last, you draw up at the old Warwick Arms Inn.

If only for a taste of life in the inns of old England is it worth the time, the money, the effort of coaching to-day. There is something about the life of these hostelries—the service, the food, the hospitality—that is different from the inns of all other nations. It is refreshing to look back upon for the rest of one's days.

You're to take dinner at the inn. Mine host is already reserving places, but while he prepares for it, you may stroll to Warwick Castle, a landmark well worth your while. Incidentally, of course, dinner is extra. The motor coach will meet you in the inn yard promptly at 2.30 this afternoon.

You loiter down the narrow passage, next the sitting room, to the dining chamber itself. Tables large and tables small, are here, crowded with travelers off the motor coaches. Even as you prepare to eat, another company here, then another and another.

There's a regular dinner served these guests, chicken, cold ham, boiled potatoes, lettuce, then a

Milking for Market.

currant tart. Some folk order coffee or a glass of English beer. The whole, with the tip, will come to perhaps 88 cents. No matter from what part of the States you may hail, the chances are you'll run across some towns folk here—people come and go in such endless numbers. Many of the visitors are off on what is known as the "Shakespeare land excursion," from London to Stratford. They "do" the castle at Warwick, then continue to Stratford that afternoon, and in the night to Leamington and on to London.

Wise travelers, however, do not travel so fast. You'll have come to Warwick and spend the whole

Digitized by Google

afternoon there; and so, now, while your seat mates "do" the castle in haste, you can chat with these towns folks or else get at your notes and have them in shape for more when they come. While you write, the odors of the "Rheinweide," an imported plant, come to you, the music of a street piano, or organ on wheels, rather, greets your ear. It is sweltering and the strollers tire easily of walking and come loitering back for the seat in the coach. The display of old pewter, the quaint signs on the walls, or out on the gate post bespeak an England that is gone.

And so with other phases of this cross England motor coaching. Every mile of it has its vignette of charm. Like one great motion picture, rural England goes past you. By and by you recall the bluff

Proud of Their Old Pewter.

Englishman angling in the stream. You remember the dairyman milking his cows in the meadows; you remember the big modern inn with the private auto before. You seem to hear again the clink of the pewter; your wanderlust stirs and you want to repeat the trip so soon as it is concluded. You want to do Wales and then Scotland in these busses. In short you would like to turn nomad and motor to the end of your days.

GARAGE TALK.

A Few Trifles, Neither New nor Novel, but It Is Well Enough to Note Them.

BY JAMES F. HOBART, M. E.

"Say, Bill! Just take a look at these burners, will you? Some of them are almost closed with something like tar. It must be mighty poor gas they are giving us nowadays!"

"No, John, that's no fault of the gas. It's the man who uses the gas who is to blame this time, and nobody else."

"I don't see how that is. I have been using the gas myself and I have done just as I always do—light it and turn it off when I am done using it."

"That's just the trouble with your burners, John. When you turn off acetylene gas very slowly and let the flame die down gradually, there is apt to be a deposit or collection of the tar-like substance of which you complain, and the deposit seems to be at the opening of each burner—just at the point where the gas flows out into the atmosphere. I don't know just how the deposit is formed, but I notice it where the lights are turned out slowly. To get rid of this trouble, just turn off the gas quickly when you put the lights out."

"Then, if that is the trouble, why don't the burners fill with the tar-stuff when the lights are left turned low for some time?"

"I can't tell you, John, but they don't. It seems only when the flow of gas dies down very slow to nothing, that the deposit forms. It may be due to a condensation of carbon at the instant the flame dies out, as then there is not sufficient heat left in the flame to support it and there must be a bit of heated carbon left which may take a semi-solid form at that instant. Perhaps some of the chemist sharps could tell why it happens, but I can't. Just turn off the gas quickly every time you put out the lights. If the tubing lies so you can get hold of it, and you will pinch it close when you cut off the gas, then there will be no tar deposit in the burners. You will find this deposit worse when you use a generator than when you use gas from the tanks. You will run up against the same thing when you are using the oxy-acetylene welding outfit. There, when the flame 'breaks' at the torch and blows through it with a terrible noise, the operator always jumps for the oxygen valve, which is close to his fingers on the torch, and shuts off the oxygen as quickly as possible. When the acetylene is turned off slowly, the same tarry deposit is found to give trouble, especially when the tubes leading to the torch are large and the acetylene gas reduces its pressure and burns out very slowly. The acetylene welder soon learns to stop all this burner clogging business by giving a puff of air from the mouth as soon as gas is cut off at the valve. This puff blows out the acetylene flame and there is no trouble from deposits of carbon in the burner."

Cylinder Scratches and Graphite.

"What d'ye think, Bill, regarding graphite for scratches in a cylinder? Do you believe a scratch can be filled up by using graphite? It looks sort of fishy to me. What is to prevent the graphite from being blown out of the scratches by the force of compression or of explosion?"

"There is something in it, John, for I know that a long continued use of graphite does smooth up a badly scored cylinder, but it can't be done in a week or in a month. It may take a year to completely fill some scratches, but the graphite will slowly build on the low places in the cylinder which are not touched by the rings as they sweep over the surface."

"But how does the graphite stick there? I should think the force of an explosion would drive out every particle of loose graphite which happened to be in one of the scratch channels?"

"It does blow out most of the graphite. Probably not one particle in a thousand of those placed in the cylinder ever adheres permanently to the surface of a scratch. But, occasionally, a particle may get caught there. It may be blown by the explosion force against another particle with such force that it is fastened thereto, and so it goes for a long time, gradually building up, one particle on another, until the scratches are entirely filled, or the walls of the cylinders are worn down to the bottom of the scratches or both!"

"But isn't there an awful lot of waste of compression through the scratches before they finally fill up?"

"Of course there is, and for that reason I want a

Digitized by Google

cylinder reground as soon as it gets scratched. I don't want to lose compression for a year while I'm waiting for a lot of scratches to fill with graphite. Me for the grinder with a scratched cylinder, just as soon as I find out it has got scratched!"

Dimming the Headlights.

"Wot're yer doin' with those two sweeping caps, Bill? Goin' to let yer hair grow long?"

"Those aren't sweeping caps, John; they are covers for the big headlights. I just slip these covers over the lamps in town, and pull 'em off when I get to country roads. You see, there is a stout elastic cord run into the hem of each cover, but I don't expect this will last long because the heat from the lamp will vulcanize the rubber in a short time, then it will be gone. But I have got some light helical springs which I'm goin' to run into the hems as soon as the rubber gives out and that will hold and won't vulcanize as rubber does."

"Say, Bill, I know some who cover the glass with soap in town, and wash it off when they get to the country."

"That's too much work, John. I don't want the lenses of my auto lamps covered with dry soap—too much work to take it off. Just mix a little corn starch and water, or whiting and water, if you want to daub up the lenses of your lamps—which I don't want to do to mine. And I have known some chaps to daub over the fronts of the lamps with the stuff they use to clean the lamps with. That made the glass look as though it was frosted. It cuts off the glare and when they got out of town, a few rubs with a cloth, causes the powder to crumble off the glass, leaving it clean. But you can't get ahead of my 'sweeping caps' for good light dimmers. They'll do for me!"

Cleaning the Engine.

"Why don't you clean up that engine while it is warm, Bill? It isn't much more than half the amount of work to clean an engine when it first comes in, hot, than it is when it has got cold. The dirt and grease come off much easier and the scraper takes hold of hot dried grease much more freely than it does of cold enamel-like coatings of baked oil. Clean her up while she is hot, Bill, and save time and elbow grease. The nuts and pins start easier, ground joints come apart better, and packing and gaskets never tear as badly when hot as when they are cold. It fact, there is every argument in favor of taking down an engine just after it comes in rather than when it is cold. Dip the parts in gasoline and wipe them off right quick as they come from the machine, and the parts are clean in less than no time. Put in a little tank which will hold all the parts of an automobile. Fill the tank with caustic potash dissolved in water, heat the tank boiling hot and dip the engine parts into the tank. The grease will vanish as if by magic! You don't have to put in a heating boiler. Just turn into the cleaning tank the exhaust from the gasoline engine which drives your shop. Or, you can pipe the cleaning tank solution right through the water jacket of your engine. That will heat the potash most of the time, and the exhaust turned in once in a while or in the morning will soon make things hot enough."

"Yes, John, I know you can clean lots of stuff in a potash tank, and do it quick and well, but Bill Smith uses such a tank and he is always spending a whole lot of time fishing in that tank for pieces he has lost in there and can't get out. I'd rather fish in the river than in a potash tank."

"No need of fishing, Bill. Just get a few wire baskets and put all the small stuff inside, then dip the baskets and there never will be any time lost in fishing for lost parts."

A Window Curtain Flap.

"Say, Bill! I wonder why this man has a flap fastened to the back curtain of his car?"

"That? That is for covering the window in the rear curtain when there is a car, or several of them, coming along behind. You see, it this way: With several cars behind, in the night, there is a whole lot of light from the big headlights belonging to the fellows behind, and that light just pours through the window in the rear curtain and frequently blinds the driver so badly that he can't see where he is going."

"But how does a headlight in the rear trouble the driver who is supposed to be looking out for things ahead?"

"Why, the light through the rear-curtain window just reflects from the wind-shield and from its fittings right into the driver's eye. Sometimes the wind-shield acts just like a mirror and the driver can see nothing but this reflected light. It is to cut off this very troublesome light that the flap is attached to the curtain. You see it is fixed so it can be buttoned up out of the way when not wanted over the window."

A Cylinder Tell-Tale.

"John, why didn't they make automobile engines with a pulse, same as a man? Then you could put your finger on the artery, feel the pulse and tell in a minute just what was the matter with the sick engine."

"Don't know about that, Bill. If we couldn't tell any closer than the doctor does, lots of times, I'm afraid your garage-hospital wouldn't have any patients. But let's see if the auto engine hasn't got a well developed pulse of its own which needs only to be felt properly in order to tell pretty accurately what is going on inside the cylinders. You will find it right at the auxiliary air valve. Just take notice of that little joker when the engine is running as slowly as you can make it go. You will notice a pulsation of the valve, which closely resembles the beating of the pulse, only much quicker and faster. Just get down where you can touch the valve lightly with the finger—the same as the doctor touches the pulse. Feel it? There you have it! A regular tell-tale of what is going on inside the cylinders, and if there be any irregularity you can soon detect it by a study of the auxiliary valve action."

Coming Events.

Sept. 24—Indianapolis, Ind., S. A. E. First Section meeting.

Sept. 24-25—Grand Rapids, Mich., track meet; E. A. Moross.

Sept. 27-Oct. 10—Denver, Colo., show; International Soil Products Exposition; Automobile Trades Association of Colorado.

Oct.—Dallas, Texas, show; Dallas Automobile Dealers' Association.

Oct. 1—Minneapolis. Minn.; track race; Twin City Motor Speedway Co.

Oct. 1-2—Trenton, N. J.; track races; Inter-State fair.

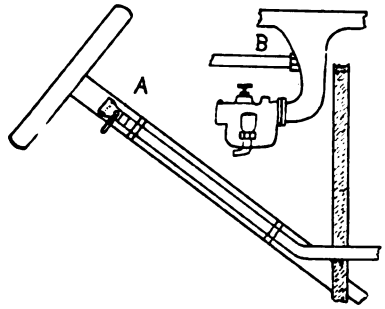
Oct. 2—New York, N. Y.; Speedway races; Sheepshead Bay Speedway Corporation.
Oct. 2—Fresno, Cal., 100-mile track race; Fresno Agricultural Association.
Oct. 2-9—Cincinnati, O., show; Music Hall; Cincinnati Automobile Dealers' Association.
Oct. 3-10—Cincinnati, O., automobile show; Automobile Dealers' Association.
Oct. 6-16—New York City, Ninth Electrical Exposition and Motor Show at Grand Central Palace.
Oct. 7—Grand Rapids, Mich., convention of the Garage Owners' Association of Michigan.
Oct.—St. Louis, Mo., show; Forest Park Highlands; St. Louis Automobile Manufacturers' and Dealers' Association.
Oct. 11-12—Dayton, O., National Paving Brick Manufacturers' Association; annual meeting.
Oct. 16—Chicago, Ill., Chicago Speedway Park Association, 300-mile race.
Oct. 25—November issue of Motorist appears; Brooklyn, New York.
Nov. 18—Arizona, 150-mile grand prix.
Nov. 29-Dec. 4—Electric Prosperity Week.
Jan. 1-8—New York City, Automobile show, Grand Central Palace; National Automobile Chamber of Commerce, S. A. Miles, Manager, 7 East 42d street, New York City.
Jan. 22-29—Chicago, Ill., automobile show, Coliseum and First Regiment Armory; National Automobile Chamber of Commerce, S. A. Miles, Manager, 7 East 42d street, New York City.
March 7-14—Boston, Mass., Automobile show; Boston Auto Dealers' Association, Boston Commercial Vehicle Association.

Home-Made Carburetor Control.



The value of controlling the air admitted through the carburetor is recognized by authorities on carburetion and a dash or steering column control is now included with the modern carburetor. Such an arrangement facilitates starting in that the mixture can be enrichened, and the control of the supply of air makes for economy of fuel in that a more homogeneous mixture is possible.

Cars not fitted with the control can be equipped at a slight expense, and the installation can be made by the average owner. The material required can be obtained at any supply house and generally much of it is stock equipment in the garage. The material consists of a nipple union, suitable length of annealed copper tubing and a petcock.

The installation is shown in the accompanying drawing. The intake pipe or manifold is drilled and tapped to take the nipple union as shown at B. The union has a pipe thread at the end screwed into the intake manifold and a compression coupling at the other end. To the last named is attached the copper tubing which is led through the dash and up along the steering column, as illustrated at A. By employing a coupling the petcock can be easily attached.

The installation illustrated was fitted to a model T Ford car, the steering post of which rotates within a tubing. This permitted of attaching the copper tubing with clips. With steering gears of the opposite type, that is, where the outside tube rotates, the copper pipe can be led to a convenient place on the dash and the petcock attached. By using solderless connections for ¼-inch tubing the joints can be made air tight very easily.

When starting the motor the petcock is closed but after the engine becomes warmed up the petcock is opened and the air supply is regulated according to the mixture and motor speed. The mileage to a gallon of fuel is greatly increased and considerably more power will be obtained as the air in striking the mixture breaks up any particles of fuel that may exist, converting them into a homogeneous mixture. The device is particularly beneficial on motors where the valve stem and guides are worn, admitting extra air, for the carburetor can be set for a rich mixture for low speeds and the mixture controlled at higher ratios. The petcock makes possible the introduction of kerosene and other carbon removing fluids when the motor is operating. It can also be utilized for priming in cold weather.

Steering column control of extra air supplied to mixture, making for power and fuel economy.

AUTOMOBILE LUBRICATION.

Carbon Can Be Avoided by Good Oil and Correct Motor Design.

C. W. Stratford before the New York Society of Automobile Engineers.—Oil for the lubrication of pistons and cylinders is splashed on the lower cylinder walls and from there it is carried upward and spread over the cylinder wall surface by the pistons and piston rings. A certain quantity as well is thrown off the pistons on their ascending stroke and projected onto the entire explosion chamber walls. If the latter quantity is small, and the fuel mixture is set on the lean side, it will be flashed off, leaving no appreciable deposit. But when an overabundance is thrown up, the heat of explosion can only vaporize the exposed surface or outer layers so to speak, of the oil film, because of its poor heat conductivity, and blow it out with the exhaust gases in the form of smoke, leaving behind heavy end-products of destructive distillation. These are rapidly reduced by the intense heat of open-throttle explosions into a cumulative incrustation called carbon deposit in common parlance. The actual free carbon content of this carbon deposit may vary from less than 1 to as high as 75 per cent. Other constituents present are metal oxides, mostly iron, from a trace to approximately 5 per cent., large percentages of inactive earthy matter (road dust) and solid black carbonaceous or asphaltic compounds, according to the oil used. An analysis of crankcase sediment, taken from a laboratory motor, showed free carbon under 2 per cent., metal dust less than 1 per cent., the remainder being nearly equal quantities of carbonaceous matter, (1) soluble in naphtha and (2) soluble in carbon disulphid. And the analysis of deposit taken from the crankcase side of the piston heads showed ap-

Digitized by Google

proximately the same percentage of the above constituents, excepting a slight increase in free carbon.

Given an oil of good quality, carbon deposits resulting from its use, up to the point where trouble occurs, can and should be easily avoided between annual overhauls by the manufacturer's proper design of motor parts. While it is a fact that much can be done toward the suppression of mechanical defects, omissions of design and carbon deposits accruing therefrom, by correct oil specifications to suit the case in hand, it is decidedly unfair to suppose that oil alone can satisfactorily replace leaky piston rings, or to burden motor oil with a more exacting task in the cylinders than that of good lubrication with its helpful seal against slight gas leakage.

Below the piston heads, though the heat conditions there are somewhat less severe than above, chemical reactions within the oil are just as inevitable and continuous. No lubricating oil exists that will not undergo a chemical and, naturally, a physical change when exposed to the high temperatures on both sides of the pistons of automobile motors. In other words, there is no motor oil known that will not deposit sediment in the crankcase. A very marked difference does, however, exist in the rate of sedimentation of oils of good and of poor quality, used in the same motor under the same operating conditions. It seems logical to conclude, therefore, that the rate of sedimentation must be a dependable measure of durability and efficiency.

Suggestions Relative to Design.

The maximum mileage per gallon of oil in the best modern automobile motor is rarely above 1,000, as compared to that of the average motor which probably never exceeds 200. Why such a wide difference in efficiency? The answer is not hard to find. An examination of the 1,000-mile motor discloses the use of tight piston rings, large centrifugal rings on the crankshaft where it passes through the case, ample cooling fins in the pistons, vents between the crankcase chamber and the valve enclosures, etc. Briefly put, cooling of the oil in this motor has been properly cared for and leakage reduced to a minimum. The result speaks for itself.

To be specific regarding details of design: Oil surplus can be kept out of the explosion chambers by leaving the lower edge of the piston skirt sharp and by the use of a shallow groove just below the lower piston ring. Small holes are bored through the piston walls at the base of this groove and communicate with the crankcase. The similarity of the sharp edges of piston skirt and piston ring to a carpenter's plane bit makes their operation plain.

Faulty piston rings are not to be tolerated any more than is their careless fitting. Concentric rings are to be preferred with a maximum clearance between back of ring and bottom of groove, of 0.010 inch. The thickness of piston heads should not only be sufficient for strength but also for good heat conduction. If the bore exceeds 4 inches thin cooling webs should be provided in the head so as to fully utilize the cooling effect of the oil. The ideal piston, from the viewpoint of cooling, is of course that made of aluminum alloy.

The cooling of oil in the sump can be accomplished most effectively by radiating fins on its outer surface. The lower crankcase should be fully exposed to the outer air. A settling basin for sediment should be provided, having a cubic content of not less than one-tenth of the total oil capacity. The depth of this basin should be at least 3 inches and its walls vertical to reduce the mixing of sediment with the oil in circulation. The inlet to the oil pump should be near and above the top of the settling basin. Concerning filtering screens there is little to be said, save that their areas should be ample and the mesh coarse enough (one-sixteenth of an inch) to offer no serious resistance to the free flow of cold or heavy oil through them; otherwise the oil in the crankcase may build up above them to an undesirable level. The necessary frequency of draining and flushing out the oil sump differs greatly with the age (condition) of the motor and the suitability of the oil used. In broad terms, the oil sump of a new motor should be thoroughly drained and flushed with kerosene at the end of the first 200 miles, next at the end of 500 miles and thereafter every 2,000 miles.

Now, to answer a leading question that cannot be passed over lightly, namely: "What is the best type of lubricating system for automobile motors?" Without hesitation I would say force feed, i. e., a circulating system with feed under pump pressure to all crank and camshaft bearings. This system furnishes a copious supply of oil for carrying away the friction heat of bearings and for cooling the piston heads. In fact, the large body of oil in constant circulation offers the best conveyance for surplus heat to the outer air. Once the oil sump has been filled, no further attention is required. There is no danger of burning out bearings or scoring cylinders from lack of oil, fouling of plugs or carbon troubles. Furthermore, so long as there is water in the cylinder jackets and oil above the oil pump inlet, no amount of punishment by hard work on the road or high motor speed can injure any of the moving surfaces in contact.

In the early days grease of medium consistency was thought to be the only proper lubricant for use in transmission and rear axle mechanisms, but improvements made in the design of different devices for retaining the lubricants where the drive-shafts pass through the case have fortunately made possible the introduction of more efficient semi-fluid lubricants.

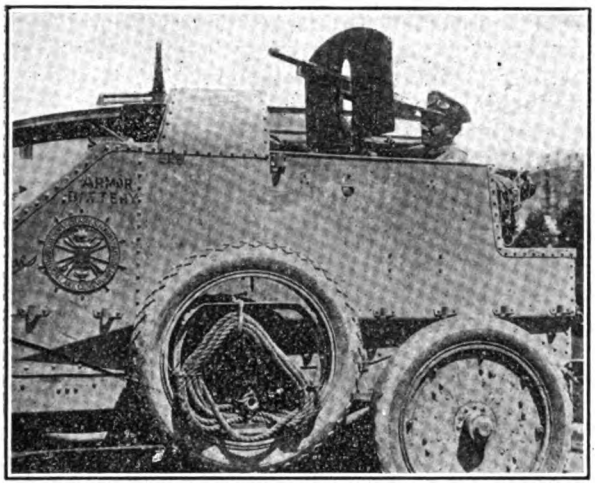
All lubricants possess a fairly high coefficient of expansion and when filled cold up to the center of the shafts will be expanded by friction heat and the level raised thereby to such an extent that the hot air above, also expanded, will force them out, even through tight joints.

As to the necessary frequency of inspecting the level of the lubricant in transmission and rear axles, or of draining and flushing out same, it would be merely a waste of words to give any definite figure. There are entirely too many variables involved. Suffice it to say that reasonably frequent attention should be given to maintain a uniform level in these mechanisms, and to drain them whenever a sample of the lubricant shows the presence of considerable metallic dust when examined by reflected sunlight. A thorough cleansing of the case between every three to five thousand miles will richly repay what it costs in lubricant by the increased life of the parts.

Commercial cup grease of a grade suiting the season should be used, exception being made only of the grease cups feeding the water-pump bearings and glands, where graphite grease gives better service.

The worm and sector in the steering-gear housing require a cup of fiber grease or a heavy gear compound, depending upon the tightness of the housing.

Digitized by Google



Preference should be given the latter wherever its use is possible.

With anti-friction bearings a medium grade of fiber grease will give entire satisfaction. In case the wheels are fitted with plain bearings a suitable grade of semi-fluid oil should be used.

Armored Automobiles.

From Felix J. Koch, Ohio.—The much-heralded Dixie Highway, the logical gateway between North and South, has given fresh impetus to all manner of matters connected with touring, and not the least interesting among these is the account of eight armored motor cars, which made the long run from North-West Military and Naval Academy, at Lake Geneva, Wis., to the great exposition at San Diego.

The long run, cross-country, was made under the direction of Col. R. P. Davidson, who is now engaged in compiling a report on the trip for the War Department. He believes that the motor car offers great possibilities in modern warfare and the trip of these cars, he declares, will have much to do with the adoption of the armored car by the United States

An American armored car, which mounts a Colt automatic gun, rapid fire. The driver occupies a compartment just in front of the gun and sees the road through a small window in the protective turret.

Army. In the train was eight cars. One is an officers' reconnaissance car, equipped with Rose military rifles, map, tables and periscope for observations behind embankments; indicators, range and elevation finders, and fire-control apparatus. The wireless car contains complete equipment which the boys are able to set up for almost instant use. Another car is equipped with balloon destroying guns. The balloon-destroyer is armored with bullet-proof steel.

Good Service and Good Tires.

How the Goodrich service department relieved a threatened beer famine on Long Island recently was told by Mr. T. A. Aspell, manager of the Truck Tire Dept. of the New York office of The B. F. Goodrich Company.

"We lay as great stress upon the service we give to our patrons," said Mr. Aspell, "as we do upon the the merits of our goods. The other day our service department in New York got a hurry-up telephone call stating that S. Liebmann & Sons' truck loaded with five tons of beer for distribution through Long Island had broken a tire near Greenpoint. This was at 9:15 in the morning. Immediately one of our auto trucks with a man from our solid tire shop was started to the aid of the disabled brewery truck. It is a forty-minute run from our branch to Greenpoint, but we brought the disabled wheel in, repaired the tire, and at 11:50 our truck was on its way back to Greenpoint. At 1 o'clock the five tons of bottled thirst-quencher were on their way to their destinations. Considering the heavy nature of the job, as well as the time involved in going back and forth from Greenpoint, I think this is top-notch efficiency."

AN EXCITING TRIP.

Automobile Driving as It Is in the Wilds of South Africa.

While he was not gunning for wild game, J. W. Kirkland, managing director of the South African General Electric Co., Johannesburg, South Africa, had plenty of opportunity to bag partridges, hares, or, in fact, monkeys, if he so desired, during a record breaking 1,097 mile trip from Johannesburg, South Africa, to Capetown, which he took recently. At one time, in fact forty or fifty baboons crossed the road so near the Franklin touring car in which the trip was made that he had to slow down to avoid a collision.

This was only one of the many interesting incidents that the party experienced in their thrilling trip across deserts and over mountains. The party included besides Mr. Kirkland, a Portuguese army officer and a mechanic.

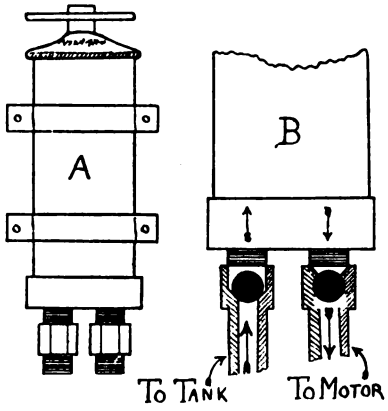
On the day of the start from Johannesburg they had traveled but 100 miles when they drove into a mass of submerged boulders. They became so firmly lodged that one of the party was forced to walk four miles to the nearest ranch house to find assistance. Five hours later, with the help of two span of oxen and some natives the party were on their way to Kimberly. Swarms of mosquitoes, even thicker than the proverbial New Jersey pests, made sleeping in the open a thing to be avoided.

For days previous to their departure rain had been falling steadily. Just before reaching the Orange River they were advised by some natives that the bridges had been washed down stream by the torrents. After considerable maneuvring around they at last found the only bridge that withstood the rains for miles around, and crossed the river over into Hopetown.

Perhaps the most exciting part of their trip occurred in the Stormberg Mountains. They were ascending the mountain after dark and had reached an altitude of 4,000 feet, when they attempted to cross what they thought was a pool, but which turned out to be a small sized pond.

In order to again gain firm ground it was necessary to enlist the aid of two young Boers, who were found sleping in a dilapidated hut a mile away from the scene of the accident. After producing a shining gold piece as a reward, they quickly stripped to the waist to lend assistance. Needing more help, the young Boers gave chase to two half-wild horses pasturing nearby, finally corraling them in true wild west style. With the combined efforts of four men and the ponies the car was brought back into the road.

In many places Mr. Kirkland experienced roads that were almost impassable, but his car ran right



Digitized by Google

along without any injury except for some scratches that occurred when going through the Stormberg Mountains.

Although held back many hours as a result of these peculiar incidents, Mr. Kirkland and his two companions established a record in going over the route in 97 hours elapsed time. This trip shattered the former record made by a member of the Transvaal Automobile Club by four days.

Auxiliary Oiler.

The supply of lubricant for motors equipped with the all loss system; that is, where the oil is poured into the crankcase and consumed, requires renewal according to the mileage. On long trips the supply is generous at first but after a number of miles it decreases. As a result the motor is flooded, then started. A reader of the Automobile Dealer and Repairer contributes the following suggestions for installing an auxiliary oiler, one that can be made at the cost of a few cents. It is fully as efficient, it is

claimed, as the manufactured oiler which costs in the neighborhood of four dollars.

The oil pump was constructed of an old tire pump which was cut off about six inches below the handle. The wooden handle was displaced and a metal one fitted as shown in the drawing at A. The bottom of the pump was removed from the tube and soldered very carefully, and the outlet for the air plugged and soldered. Two check valves of the solderless connection type were procured and fitted to the bottom part of the pump as shown at B by drilling and tapping. It is important that the valves be inserted so that they will work in opposite directions. That marked "To Motor" in the sketch allows the oil to be forced out of the pump but will not permit the lubricant to re-enter the pump. The other valve works in an opposite direction, allowing oil to be drawn from the supply tank into the pump when the handle is pulled up, but upon pushing down the handle the valve closes or seats.

The tank valve is connected to the source of supply by copper tubing, and the container may be located as desired and of any practical capacity. The pump was secured to the heel board under the front seat, and enabled the driver to force oil to the crankcase as desired. The entire material will not cost over 40 cents and if properly assembled will work as well as an expensive pump.

CARBON MONOXIDE.

The Deadly Odorless Gas That Is the Cause of Danger in Closed Rooms.

From E. H. Van Patten, Ph. M., M. D., Washington.—I have noticed several articles in your journal concerning the effects of exhaust gases upon autoists, while running their cars in a closed room, and think it might be profitable to have some one explain just what has occurred in these cases. I have had a limited experience in such cases, but enough to justify my study of the causes which are operating under such conditions. It is well known that the natural products of the explosion of gasoline mixed with air in the cylinder of a gas engine, are composed of carbon dioxide, or one atom of carbon united with two atoms of oxygen; together with nitrogen, and some watery vapor. This is what theoretically occurs when the mixture is just right. However, this condition of perfect mixture very rarely is in evidence. If there is too much gasoline for the air taken in at each suction stroke, there will not be enough oxygen to saturate all of the atoms of carbon present in the gasoline, and as a consequence some of the carbon atoms get only a single atom of oxygen, which makes an entirely different gas, and one which is much more poisonous.

It is usual for the carburetor to be set so as to have a richer mixture while the engine is idling, than when running at speed and under load, and this furnishes the exact condition for the production of carbon monoxide, which is the great cause of the danger. This gas, carbon monoxide, that is one atom of carbon united to one atom of oxygen, is a very poisonous substance. It only requires about two per cent. of it in the air to make the air poisonous.

Another thing which adds to its deleterious results, is that when it comes in contact with the blood in the lungs it forms a more stable compound with the blood corpuscles and prevents them from taking up the necessary oxygen. This is why such a small percentage of the gas in the air will cause headaches, and even death. The blood cannot get rid of it readily and the person affected dies for want of oxygen.

Some two or three years ago I was called to ascertain the cause of death in the case of a night watchman, who had charge of a railway gasoline motor car. There was no warm place to keep the car over night and as the nights were cold, there was danger of the water freezing in the radiator or the many pockets in the water cooling system connected with the car, if the engine was not run a part of the night to keep the water warm. The watchman closed all doors, windows and even the ventilators of the car, apparently in order to save the heat from escaping as much as possible. He started the engine slowly, which furnished the exact conditions for the formation of the carbon monoxide gas. The car had run off the track some time before this and without any one knowing it, there had been broken a hole into the exhaust pipe below the engine, where the exhaust gases were escaping. The engine room being sealed almost hermetically and the door between the engine room and the main body of the car being open, the heated gas rose inside the engine room and from thence found its way inside the smoking apartment, where the watchman laid down to rest. He never roused from his last sleep, and when he was found the room was filled with exhaust gases and he

Digitized by Google

was rigid in death. The condition of his body showed death from carbon monoxide poisoning.

It is this gas that is so dangerous in running a gasoline engine in a closed room, or in breathing the gas for any length of time. When a rich mixture is being used, as is necessary for slow idling of an engine, the danger is the greatest, and too much care cannot be taken to avoid breathing any air mixed with exhaust gases for this very reason.

This gas is without odor, hence is not noticed in the air until it is too late. The odor of the ordinary exhaust comes from the products of burned cylinder oil, and this must not be confounded with the monoxide gas spoken of above. The exhaust gases ought to be always conducted outside by a pipe in case it is necessary for a gasoline engine to be run in a closed room, and all joints in the exhaust pipe and its connections should be perfectly tight, in order to render it safe.

I hope that I have made it clear why these gases are so dangerous. The least ill effects that may come from the gas is a headache, but when unconsciousness does occur from breathing the gas, it takes a long time to get rid of their effects. Watchmen in these cars of which I have spoken above often complain of headache, and ofttimes they have to lay off for a few days in order to get rid of the gas which has found a lodgement in their blood. The sooner automobilists realize the extreme danger which lies in breathing this gas the better. This is my only excuse for writing this article.

So Mr. Editor, if you think you have space for this explanation, and it serves to warn others of the danger in breathing the air charged with exhaust gases, I will feel amply repaid for writing.

TIRE VALVES.

Their Construction and How to Detect and Cure Valve Leaks.

The valve is a simple but very important part of the tire, and as it does occasionally give trouble its

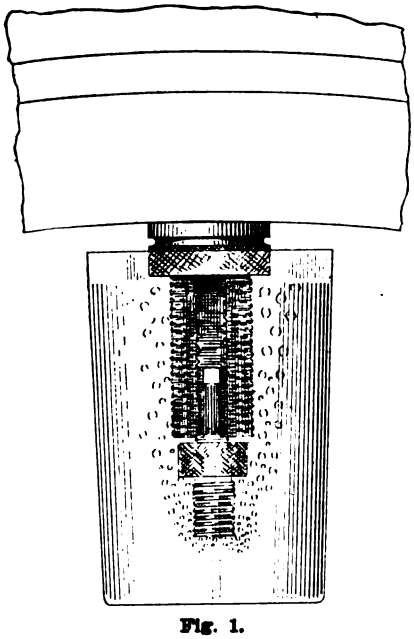


Fig. 1.

construction should be thoroughly understood. One frequently finds that a tire, which is apparently quite sound, will not hold air under pressure for any length of time. In such a case it is well to suspect the valve as the cause of the trouble, and, to ascertain if it be the culprit, the wheel should be turned round until the valve is at the top. Then both the caps should be removed and a glass of water held up to the valve, as shown in Fig. 1, so that the presence of leakage can be ascertained by the passage of bubbles. If a leak occur, the effect of screwing up the milled nut, A, Figs. 2 and 3, should be tried. The valve should then be again tested, and possibly the trouble may have been cured.

If, however, matters have not been improved, the valve must be taken to pieces, a simple matter, and a new washer fitted, also an easy job. A novice may hesitate to take a valve to pieces to remedy the defect, but he will find that the parts are few

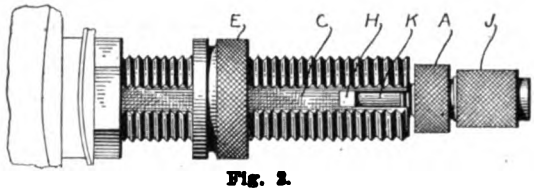

Fig. 2.

and simple, and there is no likelihood of any permanent damage being done.

To take the valve apart the milled nut, A, is unscrewed, exposing the short tube, B. This is then pulled out of the body, C, of the valve, and the needle valve, D, will come away with it. These parts are all shown in Fig. 3. The valve body, C, and the nut, E, are, of course, left undisturbed.

The parts of the valve are now all exposed, and they will be seen to be plain, straightforward elements which should give no trouble. The needle, D, carries a rubber block, F, which is conical in shape. This needle lies inside the tube, B, so that the conical block, F, closes one end of the tube, B, shown in Fig. 3, due to the block, F, not seating properly through the needle being bent or through dirt on the rubber block. Or the washer, G, may have perished.

To ascertain which of the two is at fault, if the cause of the trouble is not obvious, the valve, D, must be put in position in the tube, B, and the tube must be refitted to the valve body, C. To do this the tube must be slipped into the body so that the shoulders, H, lie in the slots, K, and the milled nut, A, is then screwed up tight. The tire should be inflated and the tumbler of water again used. To ascertain if the air leaks past the rubber block, F, the tumbler is so held that the water just covers the end, I, of the tube, B. If bubbles are seen to issue the air is obviously leaking past the block, F, and passing along the tube, B. Next hold the tumbler higher, so that the water completely covers the slots K. If the leakage takes place round these slots the washer, G, is defective.

Practically speaking, this washer and conical block are the only two parts which can give trouble, and they are quite easily replaced. Every tire maker supplies spares, and it is well to have two or three of each type handy. Occasionally, but rarely, the hexagonal nut at the end of the valve body, C, becomes loose and leakage may occur at this point. This trouble is not likely to occur during use, unless the tire is running more or less deflated, but it is always advisable to ascertain whether the nut is tight before fitting a tube, either a new one, a spare,

Digitized by Google

or one that is to be refitted. It is obvious that leakage along the tube, B, can be stopped by closing the outer end, I. In the cap, J, is a small rubber block, and as the cap is screwed on to the tube, the block closes the end of the tube, I. The closure at this point is really only a safeguard, and too much reliance must not be placed upon it. The conical block, F, should do its duty unaided, but if it does not seat properly, and it is inconvenient to replace the valve needle, one should see that the rubber block in the cap, J, is in good order, and screw the cap tightly home. The rubber blocks in these caps do not last long; often a leather block gives better service. The sleeve, L, is only a dust cover, and not intended to assist in retaining the air.

If, therefore, any particular tire is found to lose pressure every two or three days, it is well to follow out the treatment mentioned. A rough test may be

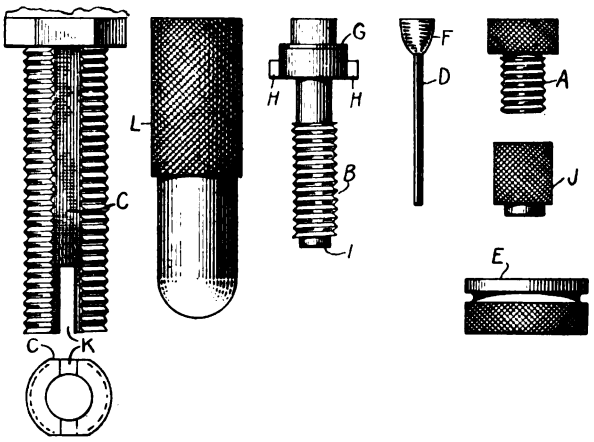

Fig. 3.

made by removing the caps, L, and J, wetting the finger and holding it to the end, I. Bubbles will indicate whether there is any escape past the block, J, but without a tumbler of water it is difficult to ascertain if there is any leakage past the washer, G. The milled nut, A, should be inspected and tightened up occasionally. The valve parts of different makes of tire are not always interchangeable, so it is well to keep the parts of different makes separate.

It is quite possible to tell if a tire cover has been overloaded, that is to say, if it has been used on a car which is too fast or too heavy for the size of tire used. A tire which has suffered from overloading commences to give way in the casing; the threads break all round inside, and if a careful examination be made frayed lines will be seen which, though not very noticeable, yet when once seen can always be recognized.

Poisonous Auto Gases.

From George S. Boucher, Virginia.—I have read with interest your article in the June issue on "Auto Gas Poison," by Lester Curtis, M. D. This is the first article I have ever seen on this subject, and I thought possibly by relating my experience I might save some person's life. In the first place, I have always been very healthy and strong, and the thought of being poisoned by auto gas had never entered my mind. I was working in my own garage and had the motor running part of the time. It being a rather cold day I had all the doors closed, and evidently was overcome by this poisoned gas that the doctor writes of. One of my little boys, who was passing the door, heard me fall, and summoned help, and it was several hours before I could walk. However, I have entirely recovered. The doctor who attended me at the time said it was likely from the exhaust gases from the car, but I do not really think that he was aware of the real poisonous nature of these fumes. I have been in a good many tight places, and had a hard fight with typhoid fever, but in my 41 years I have never been quite as near the "Getting-off-place," as on this particular occasion. I wish to add this to the doctor's warning, that any gases that will put me in the shape that I was in on that day, will seriously interfere with the regular running of that little motor on which each man's life depends.

THE JITNEY BUS FUTURE.

It Will Finally Occupy a Place Between Street Cars and Taxicabs.

From Automobile Chamber of Commerce, New York.—There does not seem to be the slightest doubt that the jitney bus marks the entrance of one of the most wonderful of our modern inventions into a further field of usefulness from which it is not going to retreat even though the surprise to the public that it can be so used is perhaps a little greater than the surprise which has accompanied the several other stages of the automobile's development.

At a five-cent fare or even at a ten-cent fare, the flexibility of service supplied by the motor car and the service rendered to the public during rush hours and over routes not covered by street car lines, counts for its increasing use and the demand of the public that its use be fostered and not hampered by legislation of a confiscatory nature.

The use of the automobile in carrying passengers for a five-cent fare is said to have originated in the West. One story is to the effect that a public driver, while proceeding down town in a Western city, noticed groups of people on corners waiting for street cars, that service having become interrupted. It occurred to him to pick up a load at the same fare as charged on street cars, which he did, going back for other loads. With this start he made a practice of carrying passengers in this way and put additional machines in the service. Other drivers noticing this did the same. The idea spread to other cities and similar service is now in effect at different points throughout the United States and Canada. While there is no definite record, it is known that several hundred are in operation in such places as Los Angeles, San Francisco, Oakland, Houston, Kansas City, Omaha, Atlanta, New Orleans, Birmingham, Philadelphia, Baltimore, Providence and Toronto, Vancouver and Winnipeg. But however interesting the origin of this service may be it is now of about as much importance as the events which led to the discovery of steam. The main fact of interest to the public is that this new form of transportation service is here, and it is the advantages to be derived from it that now demand attention.

While the advent of the jitney bus came suddenly and as a great surprise to most people, and with accompanying criticism and prophecy of failure not uncommon in such matters, it was not equally surprising to those who have been in touch with the development of the automobile industry. We all

Digitized by Google

know that the automobile itself was at first looked upon as a freakish sort of thing which pessimists conceded would be well enough as a sport for the wealthy, but those who devoted their time and money to its future development at that time first foresaw a more general use of the automobile and later were ahead of the general public in realizing its ultimate perfection, its further usefulness and necessity and the improvement in manufacture to a point where the public in general could have it at a price within their reach. As these various stages of development were realized in advance by those in touch with the industry, so now the usefulness of the motor driven vehicle in handling passengers regularly at a low fare, is to their minds a certainty, although some people seem to consider that the jitney bus is a passing fancy. The present rather chaotic conditions under which the jitney buses are operating will pass, but undoubtedly there will remain a properly regulated service of this character. Much of the opposition has been of an artificial nature and voiced from a more or less selfish standpoint, but the thing that will determine the future of this new method of transportation in city streets is whether it is a public utility and economically correct, and it is in consideration of these points that it will finally be judged. The public will certainly not permit of its being denied an opportunity to demonstrate its usefulness merely because certain persons or interests are affected. If a new and dangerous competitor of traction interests has appeared, those interests must sooner or later meet this competition; they cannot hope to strangle it any more than trunk line carriers could prevent the final development of trolley systems. Each has finally come into its own portion of traffic that naturally takes to the different channels, and it is certain that a portion of traffic is going to take to the motor vehicles.

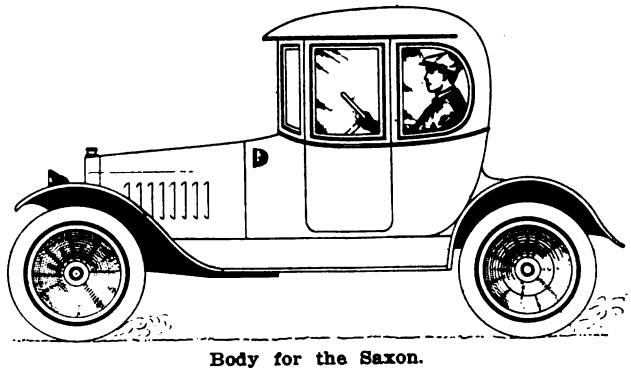
Nor is a five-cent fare necessarily a condition under which the automobile must be used in the handling of passengers. Everybody who goes to the theater doesn't elect to pay $2.00 for a seat, although everybody present sees the same show. It is quite possible that there is a middle ground somewhere between taxicabs and street cars that in many localities would result in a line of properly equipped and operated buses doing a good business at a ten-cent fare.

Some city authorities have feared accidents due to the sudden appearance of jitney buses in large numbers, but it is worthy of note that other cities do not appear to be troubled particularly in that respect, and we can see no reason why that sort of thing should continue. It may have resulted at first from a mistaken idea of drivers, possibly not as experienced as they should have been and would be under proper regulations, as to the speed they should make with their passengers, but excessive speed, in the final analysis, is certainly not going to be expected of those vehicles. It would be no trouble for them to cover a given route as rapidly as trolley cars, and their flexibility in handling would seem, in the long run, to argue for greater safety. Certainly, if they pick up a certain percentage of passengers, notably women and children,, at the curb, who now have to go to the middle of the street to take street cars, there is a possibility of eliminating a certain number of street accidents.

Some have expressed the view that the jitney bus is merely the product of a temporary condition whereby the country finds itself with a surplus of second-hand automobiles and thousands of unemployed men. If this is true, let us give one more cheer for the automobile and what it has done for the country. It is needless to recite again the growth of the industry and the hundreds of millions of dollars that it has added to our industrial development annually in its own and allied industries. If it has, at this time of business depression given employment to thousands of unemployed men in a field of individual effort, nowadays hard to find, it is something very much to be desired. But if anybody believes that all of the second-hand automobiles have been put into use and will soon be worn out, let them not forget that nearly 650,000 new ones have just been added to the supply with the close of this year's manufacturing season, and that an even greater number is anticipated for the coming year. A considerable proportion of these machinos is absorbed by persons who have old ones but who can afford to dispose of them to gratify their desire to be in possession of new ones. Whether all of the men who have undertaken to earn a living by buying second-hand machines and carrying passengers are making suitable allowance for depreciation, so as to replace their machines when worn out, is another matter, but it may be taken as a certainty that throughout the country there are automobile dealers and other capable men who will not let the opportunity pass to operate those buses where the business prospects exists, and they will not have to depend on second-hand machines to do it. The industry has reached a point where new cars can be produced at a satisfactory price and so built as to be ideal for this purpose.

Objection has been heard that operators do not give proper consideration to their methods of securing passengers—carrying signs to indicate routes, examination of their vehicles, points at which they stop, and that overcrowding is permitted contrary to the requirements of safety; but it is apparent to any one that these are details for proper regulation and do not affect the final determination of the question any more than improper operation of street cars in similar respects. Others say that the public has taken to the jitney bus merely as a novelty and that the trend will be back to the street car. This may be true to some extent, but of the many who ride for novelty, can it be expected that none of them will continue from preference?

On the whole, those who are attempting to forecast the future of the jitney bus should, to reach a sound conclusion, avoid consideration of many details which will right themselves or be controlled by local regulation. It is going to resolve itself into a straight business proposition, for, so far as the public is concerned, patronage is undoubtedly assured and to a greater or less degree according to the competition which this new service will have to meet in the way of traction facilities, and it must not be overlooked that in many places the jitney bus will supplement, rather than compete with, trolley lines.



The question is whether automobiles, new or old, and considering also the possibility of equipping old chassis with more suitable bodies, can be furnished at this stage of the industry and operated at a cost that will show a profit, assuming a proper and reliable service. On this depends whether the public will continue to have this service, which it wants,

Digitized by Google

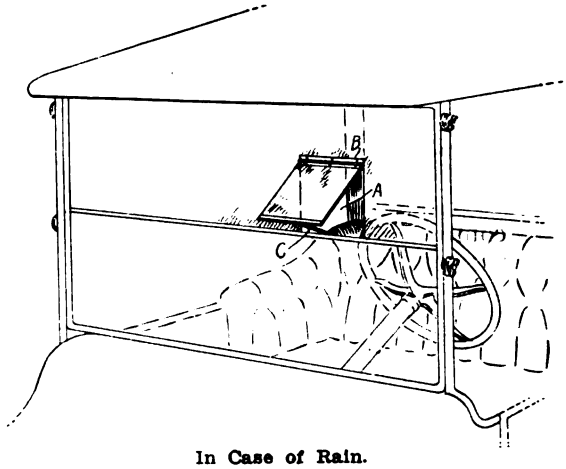
and not on any artificial consideration of its effect on the earnings and service of traction companies. If their earnings are impaired, it is only because the public, as a matter of choice, prefers this new method of transportation, and the traction companies will get back their earnings if they are in position to meet the competition; if they cannot do so, their business will suffer exactly as any other business must take its chances with competitors. Interurban trolley systems are to-day existing on business which they have taken from the railroads, and those interested in the jitney bus will see to it, so far as obstructive legislation is concerned, that they are given a fair opportunity to operate just as the traction systems look after their similar interests. To some extent the trolley lines will undoubtedly be able to hold and regain patronage; this will depend on local conditions, but it is certain that in many cases the flexibility of the automobile as to handling any new routes can and will both supplement and compete with the regular trolley lines and in many cases this service will be much preferred by municipalities and the public to a further extension of rails. The matter of license fees, routes, safety of machines and ability of drivers to properly operate them, are details that will be determined and regulated in a reasonable and proper manner.

Design for Saxon Top.

From E. G. B., New York.—The car shown in the illustration is a Saxon, two passenger, with a wheel base of 96 inches. The wheels are 28 by 3 inches, clincher tires, and has a standard tread. The seat is 16 inches deep, 40 inches wide, and 30 inches from heel board to dash. The door of the car is 18 inches wide. This design of top can be mounted on the car, and will be more comfortable in the winter season than the ordinary top. It can also be removed when necessary. In the construction of this top, it has two front window lights, two side or door lights, and two D-shaped windows each side

Body for the Saxon.

of the rear, with an oval window at the back. The top can be held in place with the ordinary fastening devices now in the market. This top can be made of metal, or the ordinary hood material, and will be found a very attractive design.



A New Cone Clutch.

One of the few original mechanical features of the new automobile models, now gaining general circulation, is the use in the 1916 Maxwell of a cone clutch, snugly housed and running in a bath of ordinary lubricating oil.

"The best test of our new clutch is the way it has satisfied buyers of our 1916 cars all over the country," declares President Walter E. Flanders. "We have given them something that will add a good deal to their comfort; that was our chief purpose in making the improvement. But we aren't losing sight of the fact that this new clutch is going to prolong the life of every Maxwell car. The clutch that grabs is as hard on the car itself as it is on the passengers. By smoothing the way for both we've done something that pleases everybody in our organization."

A Rain Shield.

From E. G. B., New York.—The ordinary windshield does not give the proper protection to the

In Case of Rain.

driver of the car in stormy weather. When the shield is closed, it is sometimes impossible to see, especially when it snows, and it has been the cause of many an accident. The writer has designed a shield that can be raised, when the main shield is closed. The glass of the main shield is cut to give a 7-inch square opening, as at A. There the 7-inch square piece cut out, is hinged to the main glass by a long metal hinge, B, which is riveted on. The rain shield is held up at any angle by a bar, C, and securely fastened. Miniature working drawings can be had at a reasonable charge, if it should appeal to the reader.

Cost of a Grade Crossing Accident.

Mrs. Elizabeth Warden Pell, who sued the Long Island Railroad Company for $250,000 for the death of her husband, S. Osgood Pell, at a grade crossing August 3, 1913, has won a verdict of $25,000 in the Queens County, N. Y., Court.

In court were Mrs. Bell, Mrs. Nathalie S. Laimbeer, who is suing for $250,000 for the death of her husband, William S. Laimbeer, and $250,000 for injuries to herself in the same accident. Augustus Van Wyck, counsel for Mrs. Pell, asked for an extra allowance of 5 per cent. of the amount as his fee. Justice Aspinall allowed this, amounting to $1,250. It was contended by the railroad company that Mr. Pell was driving recklessly. It is understood the railroad will take an appeal.

Mrs. Laimbeer's suit and that of the widow of Domenico Gambino, the chauffeur, killed in the accident, will be tried in the fall. Since Mrs. Pell's suit began the railroad company has been erecting safety gates at the crossing.

BEST TYPE OF AXLE.

Claims That the Semi-Floating Construction Has Most Merit.

J. E. Gramlich, chief engineer of the Chase Motor Truck Co. of Syracuse, N. Y., says:

"First of all, let us consider the real difference between the semi-floating and the full floating axle. In the semi-floating type, practically all of the weight of the truck and the pay load is carried on the axle drive shaft and the corresponding bearings. In the full floating type, the weight of the truck is carried on the axle housing, and none of the weight is carried on the drive shafts. In the semi-floating type, in addition to carrying the weight of the load, the drive shaft, must take the driving strain. In the floating type, the drive shaft takes only the driving strain. On the face of it, this appears to be a favorable argument in favor of the full floating type of axle. However, it does not work out this way.

"It is a comparatively simple piece of engineering to design a drive shaft capable of taking the combined bending and torsional moments which occur in the drive shaft of the semi-floating type of axle, and when the shaft is properly designed to take care of this combined load, there is little danger of breaking it due to overloading the truck and causing the axle to bend or break due to exceptional driving strains being put upon it. It is probably no more difficult to design a full floating type of axle, and make the axle sufficiently strong to take all the torsional strains due to driving, and to make the axle housing sufficiently strong to take the bending strains due to loading.

"It is, however, a rather difficult proposition to get the material to make the axle tubing, of which the housing is made of the proper size and material to overcome any bending due to loading or overloading to which practically all trucks are subject.

"This accounts for the necessity of truss rods on practically every type of full floating axle that is on the market at the present time.

"We admit that it is simpler to remove a drive shaft from the full floating type of axle than it is from the semi-floating type, but, properly designed, there should be no occasion to remove the drive shaft, so that this question can be eliminated from the discussion. Occasions arise, however, when it is necessary to remove the rear wheel, and we believe it is simpler to do this from the semi-floating type than from the full floating type, as there are fewer parts to handle.

"In the full floating type of rear axle construction, there are two ball bearings in the wheel hub, as against one ball bearing at the end of the axle housing in the semi-floating type. These end bearings serve a double purpose. First, they must carry the radial load of the truck, that is, the dead weight of the axle, the chassis and the pay load, and, at the same time, take care of the thrust load imposed upon them, due to the fact that the truck will skid and slew. Rough roads and car tracks have this same tendency to put strains on the wheels, pulling the bearings under a thrust load at all times.

"In the full floating type of axle, with these bearings mounted in the wheel rub, itself, the leverage to prevent this bending of the rear wheel, is very slight, whereas in the semi-floating type, this leverage is at one end of the drive shaft, or, in other words, in the middle of the axle housing, and the thrust load is taken care of with less strain on the bearing, than it possibly can be in the full floating type of axle.

"Owing to the difference in construction of the two axles, the semi-floating type is much more simple to assemble and to keep in adjustment, than the full floating type. The few parts in the semi-floating type make it lighter in weight, cheaper in upkeep, and more readily accessible.

"The load distribution is such that it permits of the use of smaller ball bearings, and consequently, reduced cost of upkeep of these bearings."

Starting on Batteries and on Magneto.

From Wm. J. Raeuber, Wisconsin.—I noticed in your last issue an inquiry from Mr. H. D. Pierce of New York about having trouble in not being able to get a spark when his switch was on battery but that he could get his motor to start when the switch on the coil box was on the magneto. I had the same trouble and after going to some expense by sending the magneto and coil box to Milwaukee to be tested thinking that possibly I had short circuited the magneto or coil, I solved the trouble myself.

Shortly before doing this I had trouble in starting or shifting over to the magneto, after the motor was started, and I had to run on battery, but one day I gave a rather strong shift over to magneto and from that day on I could not start the engine with the batteries, just as our friend from New York experienced. Then I sent the whole outfit to Milwaukee and all they did was to change the breaker bar and put on new points, but after I got the magneto and coil back in place I found the same trouble and so I decided to take the situation into my own hands with the following results: In the first place I went over all the wiring and connections and put in new batteries with the same results that I could start on the magneto but not on batteries. Then I took off the round metal cover that holds the switch key, plug and pushbutton in place (first putting the switch on battery to see if the contacts were right), then by taking a screwdriver and trying the circuit I found that all right by getting a spark when I tried the motor but it would not go, so I examined the contact back of the brass lever and found that it did not quite touch the last button to close the circuit for the batteries, and by simply pushing it ahead about 1/16 inch the motor started by simply making and breaking the circuit at the push button. So I had solved the whole mystery, and all it needed was to get another plug that fitted the square hole exactly, as before there was some play, the plug being worn from use, just enough not to allow of the proper contact. I did not get a new plug but took a thin sheet of brass and fitted it around the shank of the plug and flowed some hard solder around it and then filed it down until it fitted the square hole in the switch key exactly, and now it works like a charm. I have no more trouble with either the magneto or battery starting the motor. I hope this information will help the trouble our friend from New York is experiencing with the same kind of automobile.

I wish to say that since I got the switch fixed I took the breaker bar off and put back the old breaker arm just to see how much these experts from Milwaukee knew about it and I found that my old breaker arm and points work just as well as the new ones.

GASOLINE DANGERS.

The Average Person is Careless in Handling This and Other Oils.

From Oildom.—Gasoline is more dangerous than powder, is more apt to explode than guncotton, and has the explosive power of dynamite.

A recent tabulation made by K. G. Martin, of the Fire Prevention Bureau of New York City, shows that during 1913 in the United States 1,040 persons were burned to death and 3,120 persons injured (a weekly average of 20 persons killed and 60 persons injured) on account of gasoline fires. Surely an appalling number, both in killed and injured. And the injuries sustained from such fires on account of the high burning quality of the oil are in most cases severe and cause serious injuries or disfigurements for life. These accidents do not take into account the great loss in property that accompanies these accidents. Therefore, when we calmly think over these figures as a cold-blooded life and death proposition it behooves the oil man to take the role of an educator and warn the public with some of the dangers connected with oil, and particularly gasoline.

Women Should Be More Careful.

It seems almost beyond belief that women will bring into homes gasoline for cleaning purposes, which is dangerous to use under any conditions, and handle it with even less care than they would an equivalent amount of water. They are not aware that the invisible vapor from gasoline, and similar explosive fluids, will travel great distances and yet retain enough body to ignite in the presence of a spark or open flame and to flash back to the main mass of gas that surrounds the place where the work is being done and the liquid used. In such instances gasoline should be used only by an open window and then only when there is no fire in the room.

As a matter of fact it would seem a splendid policy if each State should pass laws regulating the sale and use of gasoline on the same principle as other high explosives, notably dynamite, are regulated. The public should realize that gasoline is dangerous.

According to the tabulation above quoted, it would seem that many fires originated from the cleaning of silks, due to the generation of static electricity by the violent rubbing of the silk in the oil, which produces a spark and naturally an explosion. Another great source of danger is in the automobile garage by people who feel that gasoline can be handled the same as water, since they fail to understand that the vapor from one pint of gasoline can generate 200 cubic feet of air explosive with a power equal to that of dynamite.

A very dangerous practice is the cleaning of automobile parts with gasoline from an open can. Employees find it easy to clean grease and oil from the motor and other parts with a brush saturated with gasoline. This gasoline is then readily ignited by a spark such as caused by striking two pieces of metal together, a spark from the ignition on the automobile by turning the starting crank or other cause that will create a spark.

In an instance of this kind a nut became obstinate and was struck with a wrench, causing a spark. The car was instantly enveloped in flame. The result was that the man was injured and after the fire was extinguished the car was of no further use. Backfire of the motor frequently results in the destruction of cars.

Oily waste should at all times be placed in a safe receptacle on account of spontaneous combustion. Oily waste will decay, smoulder and in time burst into flame. Sawdust, when soaked with oil drippings, will do the same thing and its use must be forbidden. Sand is the only safe commodity that will absorb oil.

Cause of Spontaneous Combustion.

In the homes spontaneous combustion caused by oily rags and cloths kept in closets is a frequent source of fire. Oil rags are used in rubbing up floors, furniture, ranges and miscellaneous metal work. The recently widely extended use of floor oiling mops has increased this danger to an appreciable extent on account of the comparatively large amount of oil which these mops hold and the considerable friction and consequent heat generated in their use. The oil on and in the fibres of the oily rags and mops, when not of mineral origin, oxidizes rapidly, and, in the confined spaces in which they are kept generates enough heat to ignite the particles of dust and dirt with which they are covered. The best way to obviate the danger of spontaneous combustion is to keep such rags and mops separated as much as possible, to remove all excess oil before putting them away and to secure ventilation for the place where they are kept by keeping the door ajar or by boring holes in the door or sides of the closet. These precautions will lessen the chances of heat being generated and the supply of fresh air will keep the temperature down to a point where combustion is not possible. Even then the rags should be kept in a galvanized iron pail.

Another source of occasional fires is caused by the use of kerosene in lighting fires in the ordinary cooking or heating stove. Kerosene should never be poured in a stove in which there is a spark of fire, neither should it be used in a stove in which the fire is out but still warm. Neither should kerosene lamps be filled while lighted, which, however, is a very prevalent practice through the country districts. Kerosene lamps with metal oil wells are safe and preferred to the ordinary country lamp with glass fonts.

Big Automobile Exports.

Figures for automobile exports from the Department of Commerce at Washington with information compiled by the National Automobile Chamber of Commerce show that for the year ending June 30, American manufacturers exported 37,870 motor vehicles, valued at $60,254,635, with parts valued at $7,000,000, making the total exports of the automobile industry $67,254,635—an increase of more than 100 per cent. over the sales for the previous twelve months, which amounted to $33,198,806.

While the greatest increase has been in trucks to European countries, passenger car exports to Europe show a substantial increase, although there was a falling off to South America and Canada. The United States exported 13,996 trucks, valued at $39,140,682, and 23,880 passenger or pleasure motor vehicles, valued at $21,113,953, with parts valued at approximately $7,000,000, making a grand total of $67,254,635.

NEW AND INTERESTING THINGS IN MOTORDOM

The Modern Gasoline Automobile.

The publishers have just issued a revised and enlarged edition of this work, bringing the information and improvements in relation to automobiles and their accessories right up to the present time. In this new 1916 edition, the subject of electrical motor starting systems has been considered at length and all leading systems and their components described. A discussion on ball and roller bearing, their maintenance and installation, has also been included, and a number of other features of timely interest such as latest types of gasoline and kerosene carburetors, cyclecar power plants, the Fischer slide valve motor, detachable wire wheels, cantilever springs, eight and twelve cylinder motors, new valve operating systems, Stewart-Warner vacuum fuel feed, Boat type body design, leather universal joints, Entz electric transmission, positive differentials, armored automobile, hydraulic brakes, etc., etc. Entirely new material has been added on tractors in three and four wheel forms, cyclecars and agricultural tractors or automobile plows; combination gasoline-electric drive, front-wheel and four-wheel drive and steer systems and other important developments in power propelled vehicles. The discussion of power transmission methods has been augmented by consideration of the skew bevel gear and two-speed direct drive rear axle, as well as several new forms of worm gear drive, etc., etc., have been added to bring the work thoroughly up-to-date.

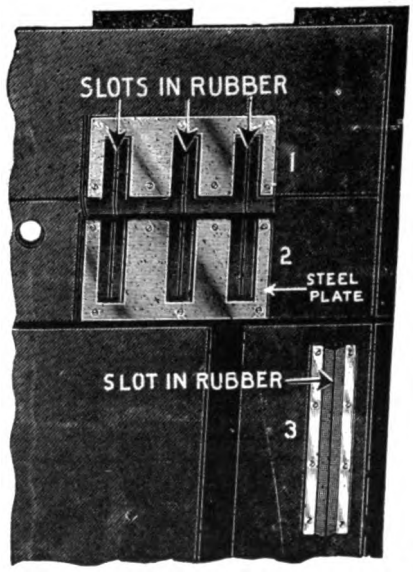
The book tells you just what to do, how and when to do it. Nothing has been omitted, no detail has been slighted. Every part of the automobile, its equipment, accessories, tools, supplies, spare parts necessary, etc., have been discussed comprehensively. If you are or intend to become a motorist, or are in any way interested in the modern gasoline automobile, this is the book you cannot afford to be without. The book contains 600 illustrations, 850 pages and 12 folding plates. The price is only $2.50. Address Editor, the Motor Vehicle Publishing Co., 71 Murray St., New York, or the publishers, The Norman W. Henley Publishing Co., 132 Nassau St., New York. Sent postpaid on receipt of price.

A Useful Oil and Gasoline Gauge.

The Charles W. Manzel Co., 309 Beard Ave., Buffalo, N. Y., has placed on the market a device to determine the proper oil level for the lubrication of the engine, and to read the number of gallons of gasoline to fill the tank. It is made especially for Ford cars. The device can be folded up like a jack knife and placed under the seat of the car, and is guaranteed to give satisfaction. Anything of this sort is likely to save quite an expense as it will prevent the cutting and burning out of bearings and ruining the motor by a lack of lubricating oil.

A New Spring Lubricator.

A handy, quick and simple tool for lubricating automobile springs is being manufactured by the Charles W. Manzel Co., 309 Beard Ave., Buffalo, N. Y. The statement is made that it will make a Ford car ride as comfortably and easy as any high-priced car. It injects soft graphite grease between the leaves of the springs and does it quickly and easily. Each application is good for 1,000 miles. The use of thin oil between the leaves of springs is not advisable, for it soon works out and wears away. The Tomahawk spring lubricator is filled with soft graphite grease, and comprises a wedge which is easily pushed between the leaves and the grease thus applied quickly. There is a guarantee that goes with this device of a refund of the purchase price, if it does not do what is stated.



Presto Car Cool.

This device is made by the Metal Specialties Co., 730 W. Monroe St., Chicago. It is made up substantially from sheet steel with slots cut in same to

Face Side Showing Lever Slots. Car-Cool Fastens Under This Plate

match the pedal slots and emergency brake lever slot on the Ford car. Between two pieces of this steel is placed three sheets of rubber, slotted, so as to allow the free action of the Ford pedals and brake lever, but at the same time

Showing the Under Side.

closing the slots automatically, thus preventing the intense heat from the engine from coming up through these slots in the foot boards and deflects the heat down and back under the car. The device is also as beneficial to the driver of a Ford car in the Winter time, as it keeps out the intense cold draughts of air, thus keeping the front of the car comfortable at all seasons of the year. It is durable and is being marketed at a very popular price. The accompanying illustrations give a good idea of its uses. It insulates the floor from the excessive heat of the engine and drives the hot air back beneath the car, closes all the lever slots irrespective of position of lever and in no way interferes with the free action or running of the car or taking off floor-boards. Each part made to fit and marked where it belongs. The average boy can attach in twenty minutes.

Accessories for Ford Cars.

The Goodrich Accessories Association, 302 North Broad Street, Philadelphia, are selling quite a variety of accessories for Ford cars, at very low prices. Among them are rear axle truss rods, break lining and wiring assembly outfits. They are of the highest grade and most approved design, and the prices are so low that they will attract close buyers who need anything of the sort. They sell scores of Ford car accessories and it would be well enough to send for their catalog, because you may find in it something you need badly.

Warm Hands Insured.

The cold weather will soon be here and if you would keep your hands warm on the steering wheel, you should under no circumstances do without the Ieco Steer Warms. They are easily placed on the wheel, and by keeping the hands warm they not only preserve the health, but make driving far safer. They save on gloves, the price is low, and they are guaranteed to do absolutely what is claimed for them. For full information address the Interstate Electric Co., 845 Perdido St., New Orleans, La.

Warner Upholstery Covers.

These covers are very attractive and they add materially to the beauty and attractiveness of the entire car. They also prolong the life of expensive leathers and insure protection to delicate finery often spotted or ruined from sticky oily leather. They also serve to cover worn, shabby upholstery and restore newness to the used car. Ever since the inception of the automobile industry the name of Warner has been connected in a large way with the manufacturing of auto parts and Warner Auto Tops have been used exclusively by some of the world's largest manufacturers. It is expected that there will be an enormous demand for the Warner Upholstery Covers, especially as they are to be advertised on a very large scale. Car owners as well as dealers should write for catalogue and in the case of dealers for samples to the Warner Auto Top Co., 1636 Central Ave., Cincinnati, Ohio.

A Cheap Protection for Stored Cars.

The Kennedy storage cover is made of heavy imported paper, reinforced so it will not tear, and is the cheapest protection that can be secured for cars in storage. It is made in sizes to fit any car. The manufacturers are the Kennedy Car Liner & Bag Co., Shelbyville, Ind.

A Strong Tire Guarantee.

One of the best proofs of the sincerity of garage men is the readiness with which they are advocating the use of Schofield's Liquid-Air. It not only stops punctures while the motorist is riding, without effort, attention or bother on his part. But it also lengthens the life of the tires. Its effect upon the tubes is such that its sponsors, the Dan Mar Corporation, offer it under a warranty that assures the owner 5,000 miles of service from his tubes.

He does not even have to buy new tubes, if his present ones are of a reliable make and comply with the liberal provisions of the Warranty under which Schofield's Liquid-Air is offered.

On the ground that a pleased customer is the best advertisement, the Company has included in its warranty even a provision covering rimcuts, blow-outs and accidents (though it is not claimed that Schofield's Liquid-Air is miraculous enough to prevent accidents). But the Company feels that it must set the pace in liberality to patrons, just as it is setting the pace in guarantees for inner tubes.

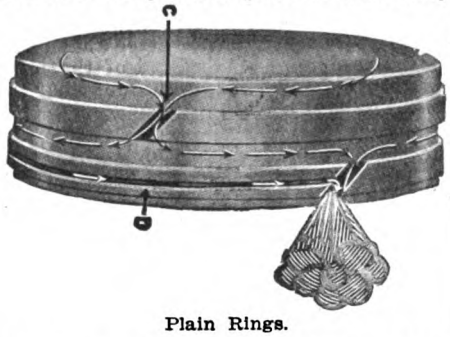
If You Want Rare Spare Parts.

The Ford-Clark Company of Cleveland, an Ohio corporation, have equipped a plant at No. 6536 Carnegie avenue for the special purpose of supplying jobbers, dealers, garage and repair men with parts formerly difficult to obtain in small quantities for repair and replacement purposes. Their line will consist in part of robe rails, springbolts, footrails, windshields, inlet and exhaust valves, hood fasteners, spring oilers, drag links and bumpers. Other parts will be added from time to time. The equipment of the machine shop is especially designed to take care of repair orders.

Starting Troubles Prevented.

The Ieco electric manifold plug, made by the Interstate Electric Co., 845 Perdido Street, New Orleans, La., is guaranteed to enable you to start your motor on the first turn, regardless of the weather. This plug is inserted in the intake manifold, and is connected with the priming cup on the dash. The current from your storage battery heats the plug. This is sure to give hot gasoline for starting and it is claimed to cut down gasoline bills one quarter, and its simplicity will commend it to the users of automobiles everywhere.

A Unique Starting Coupling.

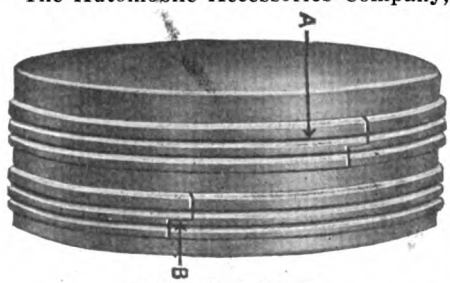


The Swiss Safety Starting Coupling is a device for connecting the magneto direct to the shaft that drives it. Broken arms or sprained wrists are unknown where this coupling is used, as there is no more danger in cranking an engine than in winding a watch. It allows the use of the Swiss single system, high tension magneto, where heretofore it could not be considered. Manufacturers of tractors, trucks and automobiles of any kind, as well as of marine and stationary engines realize its value and many have already contracted to use it. It is made by the Swiss Magneto Co., 3027 S. Wabash Ave., Chicago.

Edison Mazda Lamps.

Thomas A. Edison's dream that the Edison Mazda lamps would give a practically perfect light for automobiles, proved correct. These lamps are directly in line with the improvements which have been made in Edison lamps for the past 36 years, when he first discovered electric lighting. The Mazda lamps are made in different sizes for headlights, and in either 6-7 or 12-14 volt circuits. They are unusually economical and the light they give is as clear, white and brilliant as sunlight. Those interested should address the General Electric Co., Harrison, N. J.

No-Leak-O Piston Rings.



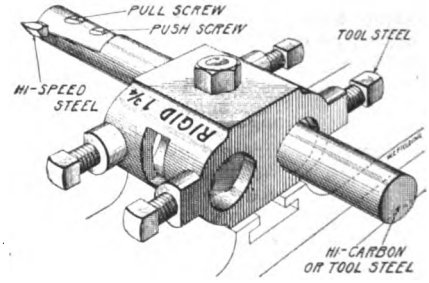
The old-style slanting cut piston rings have stood the test and have made good, but like every other part of machinery

Plain Rings.

improvements are constantly being made and the standard of efficiency being brought to a higher state of perfection. Many different types of piston rings have been brought out in recent years, each one having its special features, some very effective. It would seem that the ideal piston ring should be, first, made in one piece to insure easy installation without breaking, to have body enough to hold its resiliency under heat and not get out of place; second, made to take up sufficient oil from the crank case to lubricate perfectly, to insure long life to both ring and cylinder-wall; third, made so the oil that lubricates will form a seal all around the ring to prevent the escape of gas in order to get maximum power all the time; fourth, made to control the supply of oil so there will be no waste oil, thus eliminating carbon and oil troubles, saving fuel, grinding of valves and other repairs.

The Automobile Accessories Company,

No-Leak-O Rings.



816 West North Ave., Baltimore, Md., makers of No-Leak-O oil packing piston rings, claims the ideal ring, which is explained by the illustrations. A groove in a diagonal cut ring is not very effective, the gas air or steam that escapes through the diagonal cut C will suck the oil out of the grooves D (see arrows). Not so with No-Leak-O rings. The escape is cut off by the lap-point B, the oil remains in the grooves A, which forms a seal, preventing the escape of gas, lubricates and acts as a packing against the oil getting up into the firing chamber.

Oil Grooved Packing Rings.

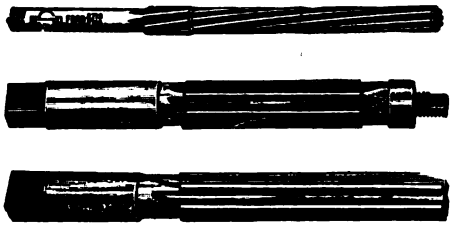
We wish to call especial attention of our readers to the self-lubricating, oil grooved piston packing rings which are manufactured by the Rittenhouse Fleury Company, 304 Holliday Street, Baltimore, Md. The manufacturers claim that these rings absolutely prevent over-heating, giving better compression, better power, decreasing friction and lengthening the life of the motor, also saving repair bills. Engine troubles, it is claimed, are largely eliminated by the use of these rings. Correspondence from dealers and repairmen is invited as well as from car owners, and this company would be glad to send their interesting free circular to any of our readers who would take the trouble to write for it.

Rigid Boring Tool System.

The boring tool illustrated here and other small tools, recently placed on the market by the Rigid Tool Holder Company, of Baltimore, Md., were designed and originally made by a mechanic in the U. S. Bureau of Engraving and Printing, in Washington, D. C., for his own use. They proved good, and the shops of all the Government departments of Washington, so it is claimed, have either given or promised an order for one or more of them. The tools consist mainly of a special lathe boring bar, in ten sizes; four types of holders therefor, to meet various conditions; a special cutting-off tool, and internal and external thread

The Double Reversible.

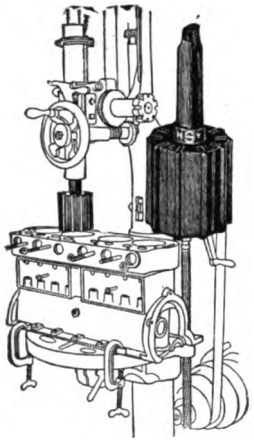
tools. The boring bar's cutter clamp power is multiplied five and one-half times by the action of the push screw. The Adjustable Boring Tool fits most any lathe from 12-inch up. All the barports are elongated horizontally. The Double Reversible Boring Tool shown has a one-piece steel holder, and is as rigid as an anvil. It reverses both end for end and upside down, giving four bar-elevations. The Single Reversible Boring Tool has another one-piece holder as rigid as possible and intended for two specified lathes only to which it is fitted. It reverses vertically only. The Tool Post Boring Tool has still another one-piece holder, and is as rigid as a tool post tool can be. The Cutting-Off Tool is obviously very rigid. It is either right or left-handed. U-shaped liners are used for elevating.



Ignition for Ford Cars.

A. J. Picard & Son, 1720-22 Broadway, New York, now have the sole rights for selling the Connecticut Automatic Ignition System for Ford cars. It gives the motor increased power, greater flexibility, renewed energy for rapid acceleration and puts starting troubles out of existence. The automatic switch, which is a feature of this system, has the same mechanism exactly as on the regular Connecticut system, the only difference being in the shape. For full information concerning prices and details of coonstruction, address the agency as above.

Digitized by Google



Some Improved Reamers.

The fitting of bushings requires a reamer, and those of the Ford car need special sizes. Stevens & Co., 375 Broadway, New York City, is producing a line of new reamers, the leader of which is the Duplex, which combines two reamers in one by reason of its construction. It is utilized for fitting the spindle body and spindle arm bushings, and provides two diameters. The Duplex is supplied with straight and twisted flutes, the latter being especially convenient for

Duplex, Plain and Expounding Reamers.

split bushings. The plain and expanding reamers are for various bushings, and the latter are ground .005-inch undersize, permitting of their use with worn or refinished parts. The reamer can be brought up to .005-inch oversize if desired. For fitting oversize pistons to the Ford cylinders the trade will find the Stevens cylinder reamer serviceable, as it is constructed with inserted blades with a cutting angle and clearance

Cylinder Reamer.

which requires but little power. The reamer can be used in an ordinary drill press. The maker states that the reamer will accurately ream a cylinder in fifteen minutes. Special body or Morse shank is supplied to order.

"The Best Lighted Car in the World."

At the opening of a fair just held in Fairfield, Conn., a parade was given in which one car was used to light the way for the parade, give light to the musicians in the band, etc. This car was equipped with twenty powerful Newtype Spotlights, each one using argon gas lamps so that the light reflected ahead on the road totaled over 500,000-candlepower. Photometric tests of the power in these lights have been made on the screen, and a 15-candlepower globe properly focused in the parabolic reflector projected 5,000-candlepower at fifteen meters ahead of the screen, and with argon gas globes the candlepower at the same distance was 10,000-candlepower. The great concentration of light projected from this small lamp was shown by a practical test made with one of the Newtype Spotlights used on a Ford car and lighted from the Ford magneto, as follows: A cigarette held in the rays directly in front of the lamp was lighted in less than one-half minute. The Newtype Spotlight locks at any angle desired, and attaches to the side of the windshield, and has the unique and original feature of having a mirror on the back of the light for use in daytime, a requirement now being enforced in a great many cities. Newtype Spotlights are one of the products of the Wood Manufacturing Company, Fairfield, Conn.

New Piston Rings.

P. H. Mish, 1790 Broadway, New York, is making the Eco New Process Piston Rings. These are of the one-piece type, and a special metal is used in making them. Each ring is closed in individually and ground absolutely round. The diameter of each ring is always up to size, and it will accurately fit and fill a cylinder of a corresponding diameter. These piston rings have an unusually high reputation, and those who have used them would not be without them. Over 300 different sizes will soon be in stock, and special sizes will be made to order if desired. For further information address E. H. Mish as above, and it would not be a bad idea to send for the little book of information and price list which this firm has just issued.

Velie Enters a Larger Field.

With the announcement of a Velie "Biltwell Six" at $1,065, the Velie Company entered a field entirely foreign to them, as heretofore Velie cars have been much higher in price and were available only to the limited class of buyers investing $2,000 or thereabouts in a motor car purchase. Now with a light six in the thousand dollar class, the factory is deluged with orders, and the dealer clientele has been greatly strengthened. Nothing has been skimped, nothing overlooked in building the new six. With 115-inch wheel base and 40-horsepower motor this light Velie covers the road in a remarkable manner. Long underslung springs, real leather and deep cushions provide a riding comfort usually associated only with high-priced cars. For over threescore years the Velie interests have been building machinery and vehicles, and their present enormous organization has been built up solely on the policy of making the products all they represented them to be and more. It is made by the Velie Motor Vehicle Company, Moline, Ill.

Portable Garages.

The Wabash Automobile Company, 1311-13 Wabash Ave., Chicago, make portable garages for $55 each and upward. No one can expect a garage cheaper than this, and those needing one should write for a catalogue to the address given above.

A Trouble Finder.

The American Bureau of Engineering, 1526 Wabash Ave., Chicago, Ill., has devised a simple card index system whereby a repairman knowing the symptoms of the trouble can, without hesitating, correct the fault. For example: If the garageman is approached by a Buick owner with a Delco System installed in his car and the complaint is made that the generator will not charge the battery properly, by a systematic method the garageman can find just where the trouble is and correct it. The Ambu, as the system is called, contains upwards of 700 cards, a certain number for each system and for each car using that system, together with blue print wiring diagrams and instruction cards for various systems telling how each unit operates and why it acts so. In all there are twenty-eight starting and lighting systems taken up. Under each of these heads are the names of the cars using it, together with the characteristics of the particular system, so that if an equipment maker builds more than one system all types are taken up. This process of correcting trouble in a systematic way, not only saves time and money, but makes far more satisfied customers because of the exactness with which the work is done. There is a feeling of security on the part of the repairman, because he can tackle any system without the fear of having to

Ambu Trouble Shooter.

say, "I cannot find the trouble." But the repairman can do more than satisfy his customers and get the name of being a responsible starting and lighting man. He educates himself because the Ambu gives instruction on the operation of the various units of each system. Some systems have inherent regulation, others use a slipping clutch, others a third brush, etc. The various types of generators and cranking motors are described under their own names. The blue prints of the wiring systems which are furnished are more than ordinary prints, for they show the various units in their relative position in the particular car upon which the work is to be done. The wire sizes are all in proportion, so that if a meter is on the dash it is placed in that position on the diagram. This makes tracing an easy matter, and any man of ordinary intelligence can follow out any circuit.

Rings at Excessive Speed.

George W. Edgar, Seattle, Wash., has perfected a bell device for attachment to motor cars that can be set automatically to sound a warning when the vehicle exceeds the limit allowed by law. It is operated by a gear attached to the speedometer sprocket, and can be regulated to ring at any speed.

Digitized by Google

Two Very Useful Books.

The Auto Electric Systems Publishing Company, of Dayton, Ohio, and 1700 Broadway, at 54th St., New York City, has brought out two unusually interesting and useful books for motorists in what they call their Information Series. Book No. 1 contains general electrical information pertaining to storage batteries, motor generators, simple principles of electricity, and elements of electricity and magnetism, while book No. 2 contains complete authentic wiring diagrams of auto starting and lighting systems used on Delco-equipped cars to date, and it contains thirty complete plates in all, together with full information relative to adjustment and repairs of parts. This information on Delco systems, they

H. G. Grove, New York City.

state, has never before been assembled or published anywhere, and it is particularly valuable to every garage man and mechanic. The price of these books is 40 cents each, and they are well worth the money. The same publishers are prepared to furnish a book covering starting and lighting systems generally, together with a chapter on charging and care of storage batteries, electrical gear shifts, and so forth, and a line of other works pertaining to automobile repairs, carburetion, ignition and timing. Address inquiries to H. E. Grove, Eastern Sales Distributor, 1700 Broadway, New York City.

Heiser Valve Tester.

This is a device to show the motorist the leaky valves and the tight ones. It absolutely shows the condition of the valve stem and the valve stem guides. The intake valve stems and valve stem guides when worn to such an extent that they admit auxiliary air cause erratic running motors, loss of power and waste of gasoline. The Heiser Valve Tester will verify the work of the repairman after it is done, and will give him the necessary assurance that the valves are in proper working condition. This tester is not only for the valves of Ford cars, but a great many others where the valve port does not exceed two inches in diameter. The price of the tester is so low that it is within reach of every motorist, and all inquiries should be addressed to the Heiser Special Tool Company, Dept. A., Kingston, Mo.

Ford Car Starting and Lighting.

A complete, ready-for-installation Splitdorf-Apelco Electric Starting and Lighting System for Ford cars for $65, is the latest offering of the Splitdorf Electrical Company, of Newark, N. J. Absolute utility has been the keynote for the strenuous and exhaustive tests the system has undergone to pronounce its fitness for hard service. In construction and application and simplicity of installation and effectiveness of operation, these outfits hold the palm for lighting-starting qualities and there is naturally a big demand for installation among the thousands of Ford owners.

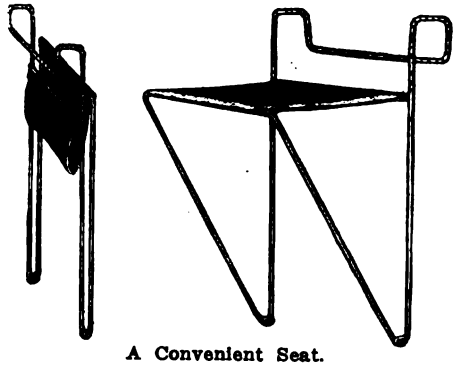
The Splitdorf-Apelco system consists of a Motor-Generator, Indicating Automatic Switch and Starting Switch, together with a 12-6 volt Storage Battery and all necessary parts for installation. As a generator, it has capacity to keep the battery fully charged, insuring ample current for starting, lights, horn, etc. In combining the motor and dynamo into one unit, a compact design is not only secured, but a design which lends itself to an easy application to the Ford engine. The armature of the machine has but one commutator, one set of brushes and one set of windings.

The use of 12 volts for starting insures sufficient power to spin the motor under normal conditions, as well as cuts down the current drawn from the battery. At the same time, 6 volts for charging makes it possible for the generator to begin charging at very low car speeds, as well as makes the use of 6½ or 7-volt bulbs possible for the various lamps on the car.

Inside Blow-Out Patch.

The Polson Rubber Company, of Kansas City, Mo., is marketing a new inside blow-out patch called the Safety First. This patch completely encircles the tube, and is fastened by an improved self-adjusting strap fastening. It is claimed when the air is applied the patch expands at the ends and tightens in the center, which prevents it from pouching and making the hole in the casing larger. The company recommends it as a positive protection against rim cuts and side blow-outs. It is made of extra

stout white frictioned fabric, vulcanized over molds, fitting perfectly. Has rubber ends as an extra precaution against pinching the tube. Length of all sizes is ten inches.



"The Winner."

By William Winter. The Bobbs-Merrill Company, publishers, Indianapolis, Ind. Price, $1.25.

"The Winner" has to do with automobile racing. Perhaps the author had Indianapolis in mind when he described "Centralia," but it might be almost any other American city whose Speedway becomes at stated intervals the scene of international contest and excitement. The intense rivalry among drivers and makers of cars affords rich material for thrilling incident, of which Mr. Winter avails himself with considerable skill. The story seems to possess the qualities of popularity, for what American is not interested in motor cars? The love plot is founded on physical attraction and natural sympathy. The style is smooth and straight. There is no pause here, no returning on the track, and a growing speed from the opening to the end of the spectacular race. "The Winner" deserves its name.

A New Auxiliary Seat for Ford Cars.

The McKinnon Dash Company, of Buffalo, N. Y., offers an auxiliary seat for

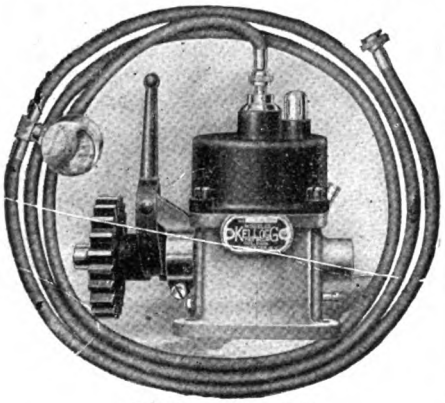
A Convenient Seat.

Ford cars. This seat rests on the door sill and hooks over the top of the door, but its weight does not rest on the door. Its frame is made of round, electrically-welded steel, and the door of the car cannot open when the seat is in place. It is called No. 90 seat, and the price is low. Those interested should address the manufacturers as above.

A Speed Crusade.

Following a series of accidents and deaths in July, a clearing house for complaints against violation of traffic ordinances by motor car drivers was formed by the Minneapolis Civic and Commerce Association. Some of the drivers who caused deaths were indicted by the Grand Jury. Three drivers were sentenced to the workhouse for reckless speed and nine jitney drivers were fined or imprisoned. Five complaints were received by the bureau in the first hour. The association sent out investigators. Twenty complaints were received the second day. Passing street cars, while standing at street intersections, overtaking and passing street cars on the left side of the street, speeding, driving without lights and stopping on left side of street were the chief complaints. At the end of the second week none had been killed, and accidents were cut to less than one a day.

Raise in the Price of Gasoline.



The big oil companies are beginning their annual raising of prices of gasoline. First in the field, the Standard Oil Co., of New Jersey, has announced a raise of one cent per gallon on all gasoline delivered to garages and dealers. The price for the present will be 10 cents a gallon, subject to another raise at short notice. The Atlantic Refining Co. immediately followed suit with a one-cent boost from ten to eleven cents per gallon, delivered to garages.

Engine-Driven Tire Pump.

The Kellogg Manufacturing Company, of Rochester, N. Y., announce that its different models of Engine-Driven Tire Pumps will be continued in its original design for 1916 because their present models are proving so satisfactory. The cylinders are of finest close-grained gray iron, and pistons are fitted with three carefully ground soft steel rings. Poppet valves are used, and it is due to this that the air delivered by the pump is comparatively cool, and no cooling coil is necessary. Poppet valves can, of course, be ground to a perfect seat insuring maximum efficiency. The bearings in the new pumps will be lined with genuine babbitt, bronze having been used in the past. The system of lubrication is especially interesting because a clever design makes possible an absolute guarantee against oil spray in the air delivered by the pump, even though sufficient oil is carried in the crank case of the pump to lubricate all bearings properly while inflating a number of tires. It is unnecessary to lubricate the pump each time it is used. The Kellogg Company claims

Kellogg Tire Pump.

particular excellence in the fittings furnished for installing pumps. A car owner should use a tire pump once every week at the least. Keeping his tires up to required pressure will give him a surprising increase in tire mileage, and be sure to give him a better adjustment with the tire manufacturer. The most reasonable, convenient and sure way to keep tires up to pressure is to have an engine-driven tire pump on the car. Inflating tires is really the hardest part of tire trouble on the road, about the streets or in the garage. The car dealer who is not selling a good tire pump is missing a good profit that would more than pay the cost of sales work. In fact, the car dealer could help pay the rent by the sale of such an accessory—or put in conveniences without drawing from regular profits. A new booklet describing Kellogg pumps is now ready for distribution. The line of Kellogg Engine-Driven Tire Pumps has been made for seven years. Their present models are all-metal pumps that are furnished for most cars at the low price of $15. Type for the Ford at $9.50; for Dodge, Chevrolet and Maxwell, $10. These prices include air hose to reach any tire, with air-pressure gauge, the necessary bracket and well-made gears and plans for attaching to each different car. These pumps with attachments are carried in stock by distributors all over the country. A list of cars and full particulars can be had by addressing the Kellogg Manufacturing Company, Rochester, N. Y.

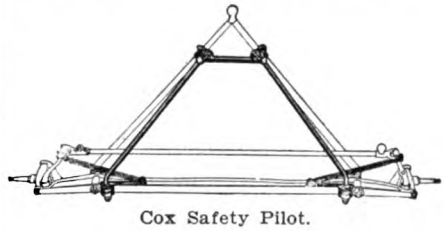
The Sears-Cross Spedindicator.

This was one of the speed meters which were the standard equipment on the 1915 Ford car, but the 1916 will not be equipped with this spedindicator at the Ford factory. It is absolutely accurate, easily mounted and can be read easily. It gives the total mileage and the trip mileage at a glance. An agency for this speed meter means a whole lot of good profit to the dealer, and those interested should secure the agency at once. Address Sears-Cross Company, Bush Terminal, Brooklyn, N. Y.

A Fully Equipped Low-Priced Car.

The Princess Motor Car Company, 1315 Belview Ave., Detroit, Mich., has increased its production of the new Princess car since the company settled in its new home, and can now insure prompt deliveries. It is fully equipped with electric starter and electric light, carries five passengers easily, and will be delivered f. o. b. Detroit for $695. This is a strictly 1916 car, and as some of the best agents' territory is still open it would be a good plan for dealers and garagemen to write or telegraph immediately for the dealer's proposition.

Liquid Air Cures Punctures.



Before offering for sale Schofield's Liquid Air, it was tested for several years in all sorts of climates and in summer and winter. The results were so satisfactory that the manufacturers now guarantee 5,000 miles service for inner tubes of this is used, covering blow-outs, rim cuts and accidents, if the reasonable stipulations are complied with. It stops punctures while the car is in use, and positively prevents slow leaks. Garage keepers should get in touch with the manufacturers and let them show you how they can increase your business. If you are a motor car driver or owner, they can likewise show you how to save money, trouble and disappointment. Address the Dan-Mar Corporation, 1790 Broadway, New York.

The New Series Genemotor.

Among the improvements recently incorporated into the genemotor equipment for starting and lighting Ford cars, is a method of insuring that the battery begins to charge at a lower car speed than formerly. A novel form of cushioned sprocket has also been devised which practically eliminates chain trouble of all kinds. The reduction of speed at which battery charging commences has been effected by changes in the electrical characteristics of the genemotor, and by the employment of an improved reverse current cut-out of simple and durable design. The advantages of this lower charging speed will be particularly appreciated by those who habitually operate their cars at fiftten to eighteen miles per hour or less. The cushioned sprocket which has been so effective during the past season in insuring quiet chain operation without loss of power has been much improved in details of construction. The latest model of this sprocket operates with the utmost smoothness, and remains in adjustment almost indefinitely. It is so constructed that slip is impossible, even when the car is running at very high speeds. These improvements assure a fully charged battery under all conditions of operation. Many minor improvements, all contributing to the reliability of the system and the convenience of the user, have also been added. For description, price and full particulars address A. J. Picard & Co., 1720 Broadway, New York. The genemotor is very extensively advertised, and promises to be one of the "best sellers" among automobile accessories during the coming season.

A Combination Accessory for Fords.

The "Safety Pilot" for Ford cars, made by the Cox Brass Manufacturing Company, of Albany, N. Y., is a front axle and radius rod support combined with an automatic steering device. Equipments of this character have previously been sold separately as entirely distinct attachments, and at a much larger price. This combination attachment sells for only $3.75. The Cox "Safety Pilot" for Fords is a quickly and easily attached accessory which not only prevents the possibilities of the bending out of line of the radius rods, thereby preventing the breakage of the axle under strain and materially strengthens the car, but also, through the steel spring steering device, makes driving at any speed safer and easier on account of the stabilizing springs. The radius rod support is attached to the front axle and clamped to the rods near the apex of the triangle formed by their junction, acting as a

Cox Safety Pilot.

stay or brace against all strains or jars. The automatic steering device is attached just inside the radius rod supports on the "I" beam axle, connection with the clamp of the radius rod, and consists of a flexible and an extremely strong tempered spring. This acts as a stabilizer, prevents the car from swerving on rough or sandy roads, automatically straightens the car and holds it straight, and overcomes the necessity for a continuous tight grip on the wheel.

Horns and Pumps.

Owing to an increase in the volume of business and the addition of new specialties to their line, the Oakes Company, of Indianapolis, Ind., have increased their capitalization from $50,000 to $75,000. The officers of the company remain the same. The Oakes Company are manufacturers of the Beartone Horn and Fan-Horn Pump, license brackets, etc.

Automobiles for Rural Mail.

Two hundred and eight automobile rural postal delivery routes were inaugurated about August 1 by the postal authorities at Washington, with approximately 11,440 miles of roads to be traversed six days a week by this means of conveyance. Other authorizations include eighty-three routes effective September 1 and five more, effective October 1. The routes vary from fifty to sixty-four miles, and will be operated from nine to twelve months a year. Reports received by Postmaster-General Burleson from a special inspection of two experimental routes show that this service is in every way satisfactory.

Digitized by Google

Motor for the Trade.

The Weidely Motor Company, of Indianapolis, Ind., has a new "12" motor, from design of George A. Weidely, with a bore of two and seven-eighths inches and a stroke of five inches. The cylinders are cast in threes, but the cylinder heads for all six cylinders of one group form a single casting. Aluminum alloy pistons and tubular steel connecting rods are used to permit of high speed.

An Improved Speedometer.

J. H. Cove, 600 Third Avenue, North, Nashville, Tenn., has invented a new speedometer and safety device for which a patent has recently been issued. It is to be used with the ignition circuit of automobiles or with the motor circuit of electric automobiles. It shows the speed, the season, and the trip mileage and at the same time it will absolutely control the speed of the car. By inserting the key and setting the small hand for any given speed desired, the driver cannot exceed the speed indicated by the hand on the small dial. Then, by setting the hand at the speed limit, the controlling mechanism has no control over the car. And again, by setting the hand at the starting point and removing the key, the car is thereby locked and cannot be moved by its own power. Each machine is designed with a barrel of a different shape, and a key to correspond, so that the mechanism cannot be tampered with. The retail price to consumers will average about the same as the price of other first class speedometers. The inventor has not yet had time to arrange for their manufacture, and would like to get in touch with some reliable manufacturer, with the view of having them made and exploited, either on contract or on a royalty basis.

Deaf Mutes Must Not Drive.

A precedent has been established by the New Jersey Department of Motor Vehicles, which has revoked the driver's license of C. H. Over, Jr., of Asbury Park, a deaf mute. The ruling states that a deaf mute is not competent to operate a car. The use of special mirrors mounted on each side of the windshield of his car, so that he could see cars approaching from the rear on either side, was not sufficient for a license.

Big Studebaker Earnings.

Studebaker earnings for the first six months of this year are being estimated in trade circles here and in Chicago at nearly $6,300,000. The second half should be better, because the plant improvements are largely completed. The corporation requires approximately $900,000 for its preferred dividends. Net earnings, therefore, of $6,300,000 for six months would leave $5,400,000 for $27,000,000 common stock. This is equal to 20 per cent. for the six months, or at the rate of 40 per cent. for the full year.

A Greedy Thief.

Sheriff George Flesher, Bloomington, Ill., has received the following self-explanatory letter: "I want to notify you to look out for a Ford car that was stole from me by Dale Hardy. He also stole my wife and baby. My wife has a small pointed wart on her nose, down on the point of it. She also humps her shoulder when she walks. He also took my wife's suitcase, which has a small hole punched in the side. There is a warrant out for his arrest. Notify Charles Crane, Blandinsville, Ill."

Scripps-Booth Enlarges.

Ground has been purchased and work is now going forward on a new three-story fireproof factory for the Scripps-Booth Company, of Detroit, that will permit an increase in its capacity to 100 cars a day. During the single short year of its existence the success of the company has been remarkable, and has clearly demonstrated the wisdom of its policy of seeking by an exclusive and highly original design to attract to the low-price field large numbers of purchasers.

For Starting With Magneto.

The Eisemann Magneto Company, Brooklyn, N. Y., is placing on the market a device which causes a standard magneto to produce a hot spark, regardless of how slowly the motor is cranked. It is intended especially for heavy motors used on trucks, tractors, etc., though it may be employed on passenger cars as well. The production of a hot spark regardless of cranking speed is produced by automatically compressing and releasing two springs which are part of the driving mechanism and which give the armature a sharp twist and thus cause the spark to occur at the proper moment. At speeds above 120 r.p.m. the device is automatically drawn out of action. The device can be attached to any model Eisemann magneto.

Electric Cars Without Batteries.

The Walker Vehicle Company will sell its 1916 Chicago electric passenger cars with or without batteries, deducting $270 when sold minus the batteries. Arrangements are being made to rent batteries in this city at $20 per month the first year and $16 per month the following years. The concern renting batteries agrees to keep them in repair, and if the battery capacity falls below 80 per cent. it will renew the parts free. This plan may soon become general. It makes it possible for dealers to sell electric cars without battery equipment, and naturally enables them to quote prices all the way from $200 to $900 less per vehicle, depending on the style and size. What the reduction in price will enable the electric car dealer to accomplish and what the battery rental service will do in the way of making electric cars more desirable are at the present time sources of speculation.

Most Cars to Go to Farmers.

It is estimated that 50 per cent. of the 2,000,000 motor cars in use in the United States are owned by farmers, and the percentage is increasing each year. It is estimated that 60 per cent. of the 1915 output will go to the farming communities.

Maxwell Car Oil.

A special oil known as "Maxwell Oil" is being placed on the market by the Wolverine Lubricants Co., 80 Broad Street, New York, under a special arrangement with the Maxwell Motor Co., of Detroit. Each can and package bears the Maxwell trademark. The exclusive right to use the trademark as applied to oils was given on account of the quality of the oil submitted and its suitability for Maxwell cars. The oil is exclusively recommended in the Maxwell instruction book, and is sold only through Maxwell dealers.

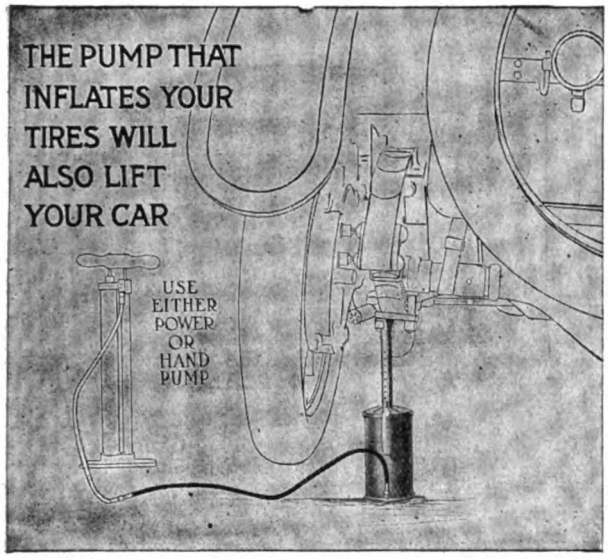
Selling Cars on Credit.

Not a few of the buyers who have purchased cars under the deferred payment plan have had to pay almost usurious rates of interest or premiums for the accommodation. The result has been that they have had reason to feel that they paid considerably too much for the car, even considering the fact that part of the payment for it was deferred. On the other hand, dealers have been badly victimized in their deferred payment selling, through being too trusting and through not knowing how to safeguard themselves in a businesslike way. To correct these two evils the bigger companies that have tackled the question are preparing standard forms for the handling of deferred payment sales, and are assisting the dealers either to make satisfactory connections with their local banks or to make arrangements with financing companies organized by the motor car makers themselves. The purpose of the car manufacturers is to prevent the retail buyer being mulcted because he wants time on part of his payments, and also to widen the selling field for the dealer by enabling him to handle the deferred payment trade without loss or too heavy investment.

Carbon Neutralizers.

Alvord's Motor Tablets, it is claimed, have increased gasoline mileage 20 per cent. These Tablets are added to the gasoline in the tank on the machine. They neutralize the carbon and carry it out of the cylinders. They help compression and stop knocks caused by carbon. Keep spark plugs and chambers clean, giving better combustion. They are made by the Alvord Sales Co., 80 Terrace, Buffalo, N. Y.

Automobile Sheet Metal Parts.



The Clayton & Lambert Manufacturing Company, of Detroit, Mich., manufacturers of the C. & L. patented line of fire pots, torches and braziers, and operating a large plant including foundry, machine shop, stamping, electric welding, plating departments, etc., have recently added a new Sheet Metal Stamping Department. They will manufacture automobile fenders, hoods, tanks and all other sheet metal parts, with the exception of radiators. They are also prepared to manufacture light stampings and to do enameling. In the new stamping department a full line of latest improved machinery and tools have been installed, and it is under the supervision of trained men, expert in this line, and they are manufacturing high-grade sheet metal products and are ready to receive from manufacturers their blue prints for quotations.

Improved Automobile Hood.

The Superior Lamp Manufacturing Company, of 136 West 52d St., New York City, respectfully notifies the trade that a patent has been granted to Harry Futterman on an improved automobile stream-line hood, which patent is controlled exclusively by them. All infringements thereof will be prosecuted. They are compelled to take this course to fully protect their numerous customers and patrons, who have purchased and are using Superior stream-line hoods for Ford cars.

Digitized by Google

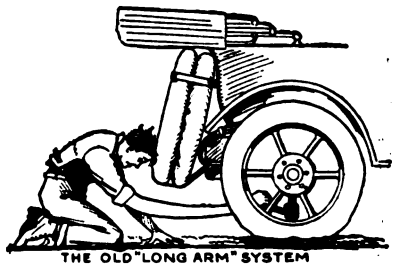
NATIONAL PNEUMATIC JACK

"JUST WHAT I HAVE BEEN LOOKING FOR"

—Is what people are writing us every day

HERE IS A JACK THAT WILL LIFT THE LARGEST CAR WITH NO WORK, NO DIRTY CLOTHES, NO "GETTING DOWN ON ALL FOURS" (like the man in illustration below).

THE "NATIONAL PNEUMATIC JACK" IS AS FAR AHEAD OF THE ORDINARY LEVER JACK AS THE SELF STARTER IS OF THE OLD CRANK.



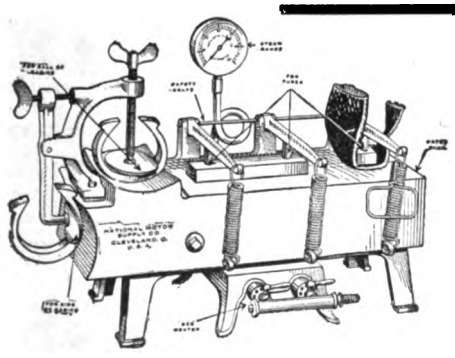
Just slip it under your car, attach either a hand or power pump to the end of hose, and up goes the heaviest car, AND STAYS THERE UNTIL THE AIR IS RELEASED. Has locking device for holding up car in storage. It can't slip. It won't sink in ground on account of its large base. You need not worry about long springs, rear tank, etc., being in the way. Five to ten strokes of ordinary hand pump will lift car. Order one for your old car, or specify that your new car be equipped with it.

Tell the agent he must furnish one with car—and he will.

Ten Days' Free Trial

Will ship one on trial, and if not satisfactory will refund your money. That's fair! Weight only seven pounds. Four inches in diameter, eleven inches high when closed, with six inch lift.

PRICE, by mail prepaid, $6.00



THE OLD "LONG ARM" SYSTEM
IS THIS THE WAY YOU WORK?

Garagemen

This is the jack for you. Just stick on air line hose, raising car instantly, with no slipping, skinned knuckles or hard work. Earns its cost in time saved. Nothing to wear out or get out of order.

Get the agency in your town.

GARAGE AND REPAIR MEN, LOOK!

Thousands of garage men all over the world are making big profits with the

NATIONAL GARAGE STEAM VULCANIZER

Vulcanizes three tubes and two casings at a time. Heated by either gas or gasoline. We have made this machine without any change for six years, which shows how satisfactory it is. You might as well have the big profits for vulcanizing in your vicinity. The National is the easiest and cheapest machine to operate on the market.

Casey Running Board Braces for Ford Cars.

With every Ford automobile sold, whether for business or pleasure, it seems to be a dependable certainty that the car will be overloaded sooner or later simply because it is such a faithful little performer in speed, power and endurance. The Casey Asco Manufacturing Company, of Kansas City, Mo., is marketing a new chassis reinforcement of unusual merit, known as the Casey Running Board Brace. This economical insurance against wear and tear from

Sturdy and Rigid.

overloads and strains, while adding but four pounds in weight to a car, will make a Ford chassis as sturdy as a truck, and permanently retain this desirable rigidity. The Casey Running Board Braces, as here illustrated, are a positive and practical remedy for this deteriorating wear, while for commercial uses where Ford cars are put into delivery service, or heavily loaded for touring, etc., these braces are a necessity for safety. The dotted lines illustrate the exact teeter and buckle of chassis as you step on any regular Ford. Just try it on your own. The solid lines show how sturdy and rigid Casey braces will make it, even though you test it by jumping upon the step with both feet. The constructive design is based on the sound principle of three-point structural steel trussing. It is indeed surprising how sturdy and quiet a Ford automobile can be made with this little reinforcement. Casey Running Board Braces will be sent prepaid on all cash orders received within the next thirty days by the Casey Asco Manufacturing Company, 1500 Grand Ave., Kansas City, Mo. Price is $2 per complete set. Can be put on by anyone in a few minutes. No drilling or fitting necessary. All you need is a wrench.

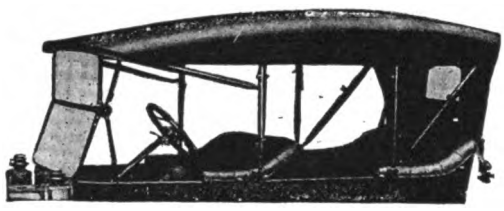
A Nice Dividend.

The Haynes Automobile Company, Kokomo, Ind., has just completed a prosperous year. A 20 per cent. cash dividend for the fiscal year ending June 30, 1915; a 2 per cent. cash dividend for the month of July, and a 100 per cent. stock dividend have been declared, as well as a 1 per cent. cash dividend for the month of August. The company has just filed notice with the Indiana Secretary of State of an increase in capitalization from $600,000 to $1,200,000.

Creditors Get 100 Per Cent.

The Consolidated Car Company, Detroit, Mich., organized to take over the business, good-will and other properties of the Abbott Motor Company and to assume the indebtedness of that company, has just completed payments to the Security Trust Company, trustees of the original Abbott company, covering a full 100 cents on the dollar to the creditors. The creditors' claims amounted to $64,000. Within the past two weeks 44 per cent. dividends has been given the creditors, 34 per cent. in the first instalment and 10 per cent. as a final payment.

No Carbon and More Power.



The Noncarbene Company, 1765 Broadway, New York, manufacture a petroleum product containing no injurious substance, which it is claimed will more than pay its cost in the saving of gasoline. In addition to this, it prevents carbon and removes any carbon already formed. It is used by such firms as the Automobile Club of America, of New York, and its cost is little. A booklet of indorsements will be sent upon request. Garage keepers might well get in touch with the manufacturers with a view to selling it.

Pistons for Ford Cars.

Depuy Bros., Canterbury, N. H., make an unusually good piston for Ford cars. It is of soft gray iron, and is accurately ground so that each are of exactly the same weight and size. These rings are sold at a very low price considering their value, and owners of Ford cars would do well to consult the manufacturers when they need anything of the sort.

Cray Slip Roof Outfit and Tops.

When the top on a Ford car becomes worn or leaky it is now possible to obtain a new heavy rubber roof, quarters, back stays and back curtain, stitched and ready to slip over the old top frame, thus giving a new top at a price stated to be about one-third the cost of a top complete with bows, bow sockets, side curtains, etc. This outfit is designated as the Cray Slip Roof Outfit "A" by the manufacturers, Cray Bros., 1111 West 11th St., Cleveland, Ohio. It is made only for 1912, 1913, 1914 and 1915

Top for Ford Touring Car.

model T touring cars, and as the side curtains on most old tops are in good condition curtains are not included. Price to the trade, $7.50 each, or $80 per dozen. This concern also builds a complete extension top, made up with heavy 32-ounce black back rubber. This top is built over Ford body frame, giving a perfect fit. A very easily operated one-man top is also put out, this top maintaining the same general level while being put up as when it is in place, not falling on the front seat or going up into the air. It is staunch and rigid, and is furnished in three grades. A 512-page catalogue is offered free to all those in the trade. Every dealer and garage man should have a copy of this book.

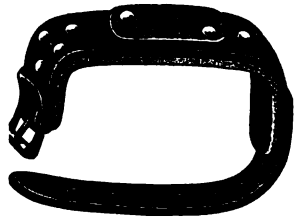
Polson Blow-Out Patches.

These tire patches are said to be unusually strong, and quite as strong as the tire itself. They fit perfectly, and the rubber end prevents pinching. They cost no more than others, and are sold by the best dealers everywhere. If your dealer is unable to supply you, address the Polson Rubber Company, 329 Southwest Blvd., Kansas City, Mo.

Waiting at the Curb.

That Des Moines, Iowa, has no pow to regulate the length of time that automobile may be left standing at curb is the decision of Judge Utterba sitting in the Iowa District Court Des Moines. The decision was given a suit brought to test the city ordinan that prohibits a motorist leaving car at the curb for more than twen minutes in the downtown district a not more than an hour in other sectio The court ruled that the city has power to regulate the standing tim and that consequently that portion the automobile ordinance is void. Th reverses the decision given bv the poli court before which the test case w first brought.

Tags Can't Be Lent.



According to a ruling of the highwa commission of Pennsylvania, motor c dealers are forbidden to lend their l cense tags to purchasers of cars pen ing the arrival of the purchasers' tags.

Canada Feels the War.

The war has curtailed Canada's impor tation of luxuries, especially in moto cars and carriages. In the last twelv months imports were $7,420,000, com pared with $18,560,000 for the precedin twelve-month period.

Spring Oiler Strap.

The Leather Tire Goods Company, of Niagara Falls, N. Y., have recently brought out a spring oiler which consists of a strap having wicking on the inside, designed to be buckled around

Oiler Strap.

the spring just inside the clip which holds the leaves together. This is the point where there is most motion between the leaves, and the oil from the wicking works between the leaves when they are in motion, keeping them lubricated, making the springs ride easier and less liable to be broken. The wicking is saturated with oil when the strap is buckled on, and has a hole in the top with a leather cover over it through which the oil can easily be squirted with the can when one is oiling the car. These Spring Oiler Straps have the advantage of being adjustable so that one size will fit all cars. They are unbreakable, are easy to put on, and sell at 25 cents each, making a full set for a Ford cost only $1. Other cars require from eight to sixteen, according to the type of springs.

Weather Strips for Automobiles.

The McCormick weather strip makes the windshield of your car absolutely weather tight, dust and wind-proof. It is adjustable to any space or thickness of glass, is easily put on or removed, and will not obstruct the vision. It is made by the Robinson Manufacturing Company, 508 Lincoln Bldg., Louisville, Ky.

Progress has put a generator on every car for lighting purposes—an instrument capable of maintaining the supply of electric current not only adequate for the needs of the starting and lighting system but ample for ignition as well.

Such a current supply has a decided advantage over the magneto's self-contained generator in that it is constant at all speeds—the magneto's supply varies according to speed.

AUTOMATIC · IGNITION
CONNECTICUT

takes its current from the storage battery of the car's starting and lighting system and not only produces an effective spark at all speeds but delivers a spark that grows hotter as motor speed decreases.

What little power the generator requires for maintaining the current supply is returned hundreds of times over in the cumulative effect of more powerful explosions resulting from more effective sparks.

Make Your FORD
An All-Year Round Car

Doubles Value of a Ford to Physicians and Business Men, who must ride in every kind of weather

Have an open car for summer touring—a classy limousine for winter. Any Ford owner will be keen to apppreciate the limousine luxury, supreme elegance and beauty of the Mandel Limosette as well as the absolute protection from storm and wind it affords. It is a flush, snug fitting top, made of wood, metal and glass. For Ford Roadster and Touring Car. Equipped with automatic rain vision wind-shield, electric dome and handsome cowl dash. Full length doors operate with one handle. Generous over hang in front accentuates the length of the Ford.

Mandel Limosette

Built exclusively for 1913-14-15 Ford Cars. Can be attached in less than an hour. Adds about 40 lbs. to weight of Roadster. 75 lbs. to Touring Car.
Gives Ford owners the luxurious convenience of a modern, high priced limousine at a very small investment.

See the Mandel Limosette at Local Dealers.

MANDEL LIMOUSINE COMPANY,
1453-1455 Congress Street, Chicago, Ill.

Cause of a Clicking Noise.

An intermittent clicking noise resembled that obtained by clicking the fingers together. The owner of the car thought something was loose, and hunted everywhere to find some mechanical defect. In one or two cases this noise was found to be due to the spark jumping at the safety spark gap on the magneto. The distributer of the magneto was cleaned up, but this did not remove the trouble as it does in some cases. The spark plugs were then examined, and it was found that the spark gaps of two of them were very wide, and at low magneto speeds the current preferred to jump the safety gap rather than that at the plug. Hence the clicking noise which alarmed the owner.

Sparking at the safety gap is generally due to excessive resistance somewhere in the high tension circuit; in this case one, or possibly two, of the spark plugs were the cause. Firing at the safety spark gap should not be allowed to continue, otherwise there is a possibility of some weak part in the armature insulation giving way. When a high-tension wire is detached from its spark plug the end should always be allowed to touch the engine, and the current thus earthed if the engine is to be run. Otherwise on each firing stroke of that cylinder the safety spark gap on the magneto will operate. This puts a bigger stress on the armature insulation than the normal operation of the magneto does.

The drive chains on trucks should be adjusted carefully. If too tight the chain will wear rapidly, and if too slack the jerks of starting will be apt to break the chain prematurely.

NEW DEPARTURE BALL BEARINGS

American Made for American Trade

Are made in four types, each in a variety of sizes calculated to meet every motor car requirement, and every New Departure Ball Bearing is *Guaranteed* in respect to material, precision and finish.

The New Departure Single Row is internationally standardized and therefore interchangeable with any foreign or domestic bearing of equal width, diameter and bore.

For Your Convenience, New Departures are stocked at our factory, at our Detroit Branch and in 49 trade centers of the United States, Canada and England.

New Battery Charger.

The General Electric Company, of Schenectady, N. Y., has brought out a new and inexpensive mercury arc rectifier which is especially designed for charging batteries such as are used for starting, lighting and ignition currents in automobiles and for other purposes where not over five ampere—fifteen volts direct current—is required and only alternating current is available. The new rectifier consists of a metal base on which are mounted the necessary reactance coils, and the rectifier tube is in a suitable cover, the whole being encased in perforated sheet metal. It is designed for charging one three-cell, one six-cell or two three-cell batteries as required, and is automatic in that it is self-adjusting to any of these three conditions. This type of rectifier can be supplied for 60, 50, 40, 30 or 25 cycles, 110-volt circuits.

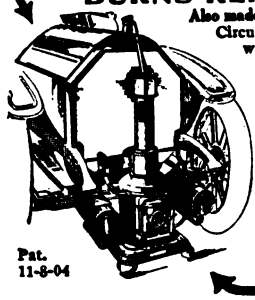
Will Now Be Made in America.

The Longuemare carbureter, which up to the present has been manufactured in France and imported here, is now to have an American model, arrangements for manufacture at Syracuse, N. Y., having been completed by the Longuemare Carbureter Company, New York. Some changes have been made to suit American requirements, and other changes which are general improvements in the direction of convenience of fitting, adjusting and assembling. The water jacket, surrounding the throttle, has been dropped, and the opening in the throttle valve for the idling jet has been increased to permit a longer dwell. There is no vital alteration in the operation of the carbureter. There are two jets, one for idling and the other for running, the first above the other. By more compact design the weight has been brought down on all models about 40 per cent. The connections are S. A. E. standard.

Gold Medal for Genemotor.

Having just won the gold medal at the Panama-Pacific International Exposition with the genemotor starting and lighting system for Ford cars, the General Electric Company, through its general distributors, A. J. Picard & Co., announce immediate delivery of the new series genemotor, which has a double point of contact relay and a flexible driving pinion.

Lights Must Not Glare.



Springfield, Mo., has passed an ordinance providing a fine of from $1 to $100, or jail sentence of from five to sixty days, or both, for using glaring headlights. Incorporated in the ordinance is a clause that prohibits the use of a revolving searchlight such as is now seen on many cars throughout the country.

The New Era Cars.

The New Era Mfg. Co., of Joliet, Ill., is casting about for a larger factory, for the manufacture of New Era cars. The local Association of Commerce has been asked to assist in finding additional factory facilities for the company.

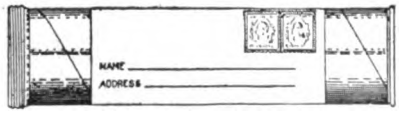
BIND YOUR
MAGAZINES
In PERMANENT BOOK FORM
We have succeeded at last in securing a really practical binder
"It's as simple as filing papers"
Our magazine contains many articles and a great deal of valuable information and data worth saving for future reference. There is only one way of keeping them.

THE "BIG BEN" BINDER

preserves them in permanent BOOK FORM. This binder is handsome, durable and convenient. It opens flat like a regularly bound book, Cloth Covered, with the name of the magazine stamped in gold. For persons who desire to



SAVE THESE VALUABLE ARTICLES

this binder is just the thing, as it can be used year after year, by simply taking out the oldest numbers and inserting the new ones as they come to you, or you can keep each volume in a binder as a permanently bound book which will be a valuable addition to your library.
By making special arrangement with the manufacturers of this best binder that has ever been put on the market, we are able to furnish them to you for

ONLY $1.00 EACH

Merely send us your name and address and enclose this amount and we will send the binder promptly, all charges prepaid.
Send in your order now and begin making the magazine doubly valuable to you, at once.

BUSINESS READING

The business man should be a constant student of the thing in which he has invested his capital, his experience and his effort. To do this he must acquire the reading habit. If he neglects this he makes a costly mistake.

The man who imagines he is too busy to read should never go into business. The chances for his failure are too great, and at best his success can never be more than a half-success.

There is no better business reading than the advertisements in this number. They are full of information and no one who is interested in automobiles can afford to neglect them.

THE NEW SERIES

Genemotor

Trade Mark

The General Electric Company announces a New Series Genemotor, now ready for delivery.

It is much more efficient than the original model, which attained leadership in 90 days.

Two important new features—a double-point contact relay and a flexible driving pinion—establish the New Series Genemotor on a new basis of supremacy.

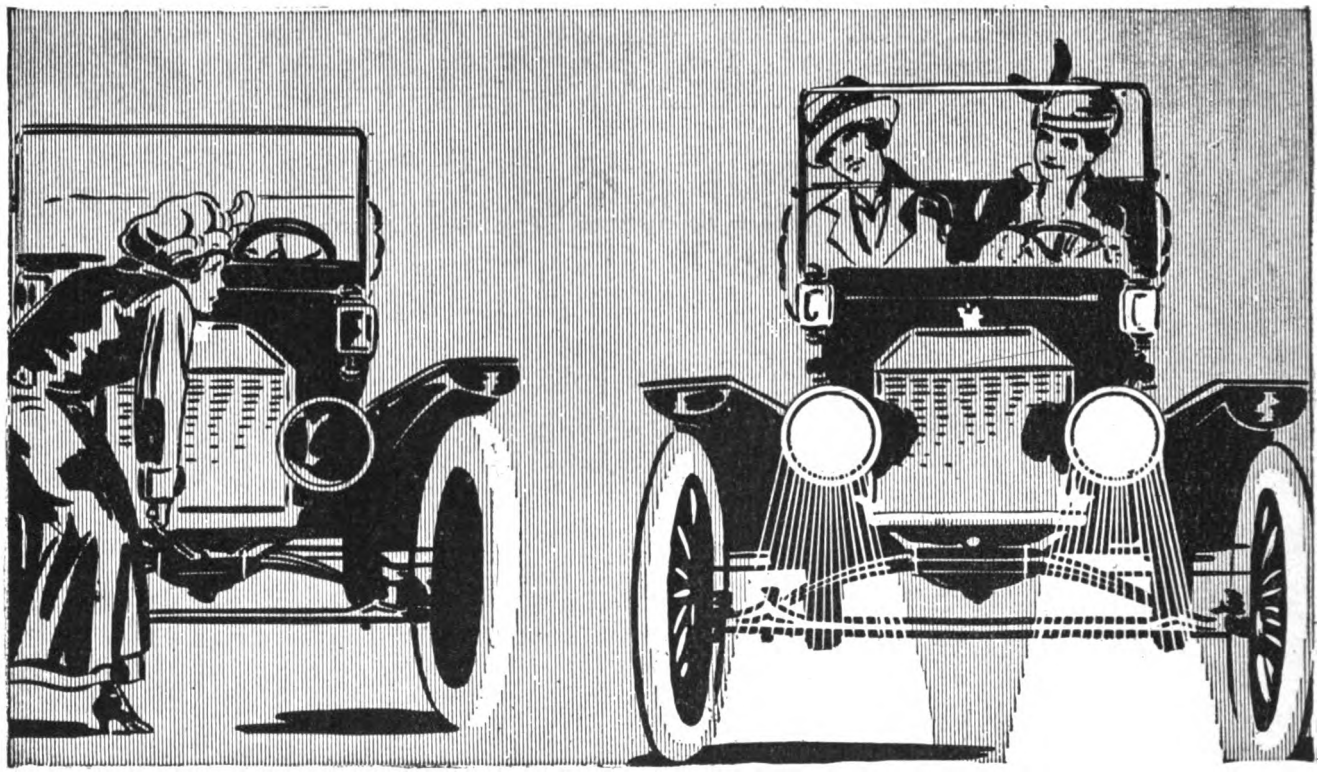
They provide against the misuse of the Genemotor in the hands of the novice and make doubly sure long and continuous service.

Digitized by Google

To the big distributor or to the small dealer the New Service Genemotor now means a big Fall season, particularly in view of the new conquest of the Genemotor in winning

THE
GOLD MEDAL
AT THE
PANAMA-PACIFIC
INTERNATIONAL
EXPOSITION

This is a distinction which has an important bearing on sales, for all the world loves a winner.



A merchant, they say, is known by the goods he sells. Why not sell the best?

If you are not now handling the Genemotor, please write us.

Women Can Drive $65

Ford cars with perfect freedom if they will be sure to see that the car is equipped with a

SPLITDORF-APELCO
ELECTRIC STARTING AND LIGHTING SYSTEM

$73 f. o. b. Pacific Coast
$85 f. o. b. Toronto

Hand-cranking with its physical strain and the ever present possibility of a back fire and broken wrist, is entirely eliminated with the use of a powerful SPLITDORF-APELCO outfit.

Just a little foot pressure from the driver's seat and the never-failing SPLITDORF-APELCO system "spins the motor" whether starting from the house or garage or quickly starting up the motor after confusingly stalling it in traffic.

The crowded city streets and the highways and byways of the country can hold no terrors for women drivers of ***Ford*** cars, so long as the car equipment includes a SPLITDORF-APELCO system—the electric starting and lighting is ***always*** taken care of.

It is simple and easy to install the SPLITDORF-APELCO system, and ***Ford*** motor repairs can be made without disturbing the installation. You can make the installation yourself or any garage or supply man will do it for you. SPLITDORF SERVICE, too, is at your command at our branch houses, and the work of installation can be promptly attended to by our own experts.

BY INVITATION MEMBER OF

DEALERS' PROPOSITION We have an attractive offering for the handling of SPLITDORF-APELCO Systems. Write for details.

The Easy Moving of Heavy Weights

The Manley Hilite Portable Floor Crane

Designed for GARAGE use and conditions

At last, a Crane at a price you can afford to pay.

At last, a Crane of one ton capacity, having the lift and overhang that is absolutely necessary in every garage.

At last, a Crane that is properly designed and built, having a light steel superstructure with a cast iron base: Result, one-half the weight—less bulk—less tendency to upset—low center of gravity.

You *now* do not have to purchase a heavy crane of two or three tons capacity in order to get the lift and overhang you must have.

The greatest time saver, labor saver and convenience that a Garage can install. It takes the place of several men.

It is an indispensable tool, as it will handle engines, transmissions, front and rear axles, etc., as no other appliance can.

Incomparably superior to a chain block and costs no more.

Besides the main features of low price, ample lift and overhang, this Crane has:

Powerful Leverage.
Double Throw Operating Handle.
Single Hoist Chain, always out of the way of the operator.
Gears Cover for Safety.
Wheel Lock.
Three Point Suspension for Base.
Unbreakable Steel Handle.
Steel Cantilever, bridge type construction.
Strength and Rigidity.
Ease of Operation.

Atwater Kent Ignition

The lifter as it is pulled forward by the notched shaft does not touch the latch, and the contact points remain open.

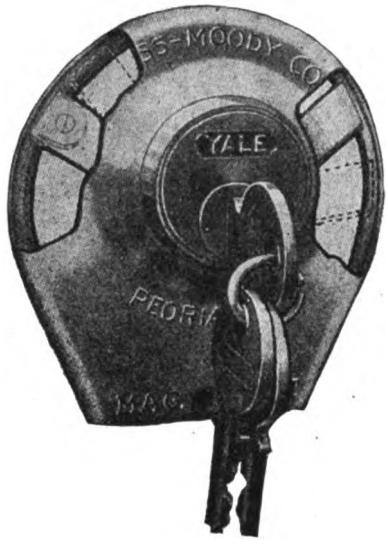
The lifter, reaching the point where it rolls off the notched shaft is pulled back by the lifter spring, striking the latch as it returns.

The latch, being struck by the lifter, presses against the contact spring and closes the contact points for a brief instant, immediately opening after the lifter passes.

The latch and lifter, having returned to their original position, are ready for the next spark.

Owing to the fact that it is impossible to stop the motor in any position which will leave the ignition circuit closed, the Atwater Kent System is fundamentally safe, and no accessory safety devices are necessary to protect the battery. The current flows only during the brief instant of each spark and the ignition switch is practically useless except for stopping the car. In other words, it might be left in the "ON" position permanently without the slightest danger of draining the batteries.

The Atwater Kent principle is absolutely unique among ignition devices. Its success is certified by more than nine years of uninterrupted growth. It is in use to-day on upwards of 200,000 cars and is endorsed by more than 30 reputable manufacturers and over 10,000 dealers, garages and repairmen.



The Atwater Kent magneto replacement system can be easily installed in place of the magneto on any standard car. Thousands upon thousands of car owners realizing the benefits of Atwater Kent Ignition are installing this system on cars previously equipped with magnetos and other types of ignition.

Our special outfit for Fords deserves the investigation of every owner of this remarkable car, and the opportunities which it offers to dealers, garages and repairmen are attracting the attention of the entire trade.

If you are a car manufacturer, dealer or owner and are not fully posted regarding this wonderful system, by all means get in touch with us without further delay. You owe it to yourself to have our complete data on file.

What's This?

THE B. M. SWITCH WITH YALE LOCK FOR FORD CARS HAVING METAL COIL BOX

1. A mechanical device that is an absolute protection against Ford thieves.
2. Installed in two minutes—by removing present switch plate—substituting this.
3. **Note:** the two brass shutters that cover the upper two deeply countersunk screw holes.
4. These absolutely prevent removing of plate and making connections to start car.
5. The Yale Key (no duplicates) acts as the switch key —automatically locking car when engine is shut off.
6. Cheapest insurance against theft.

Drive Your Car In Comfort This Winter

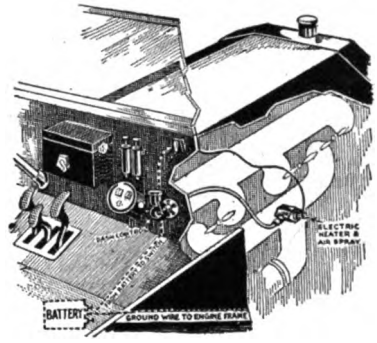
Use Ieco Steer Warms

They make winter driving a pleasure. Be comfortable. Keep your hands and whole body warm with this practical and inexpensive device. Steer Warms consist of two net leather covered grips which lace on to the steering wheel at any place convenient for driving. Special resistance wires between thin copper plates connected with storage batteries (or magneto on Ford cars) give out an even heat, enough to keep the hands warm in zero weather. They have many talking points:—

1. **Keep the hands warm in coldest weather.**
2. **Make Driving Safer.**
3. **Help Preserve the Health.**
4. **A Saving to Truck Owners.**
5. **Simplicity—No Moving Parts.**
6. **Easy to Install.**
7. **Economical.**
8. **Save on Gloves.**
9. **Price Low.**
10. **Guaranteed.**

PRICES:
For Ford Cars $5.00
For Other Makes 7.50

No More Starting Troubles



The IECO Electric Manifold Plug will eliminate your starting troubles and will always enable you to start your motor on the first turn regardless of the weather.

This wonderful electric plug is inserted in the intake manifold and a small copper tubing connects it with the priming cup on the dash—a switch at the side of the priming cup turns on the gasoline in the plug. Current from your storage battery heats the plug.

Use Hot Gasoline To Start In Winter

Gasoline flowing through the heated plug is vaporized, putting a rich hot mixture into the cylinders. There are many good talking points:—

1. **Starts Car on Coldest Day.**
2. **Primes Cylinders from the Seat.**
3. **Cuts Gasoline Bills 20% to 30%.**
4. **Tests Carburetor.**
5. **Removes Carbon Deposits.**
6. **Saves Money for Truck Owners.**
7. **Easy to Install.**
8. **Economical.**
9. **Simplicity.**
10. **Guaranteed.**

Price - - $5.00
Ford car requires 6 dry cells.

To Dealers:

Increase Your Sales During Dull Season

Persuade your customers to use their cars during winter months and increase your sales. If a motorist has Steer Warms and Manifold Plugs, which do away with the discomforts of cold winter driving, he will not be so apt to put up his car. Carry an assortment—you will sell a lot of Steer Warms and Manifold Plugs.

You Make A Good Profit

We allow dealers a liberal discount. The articles being well advertised you will sell them quickly and turn over your capital often. Steer Warms and Manifold Plugs are easily handled. They are easily demonstrated. They explain and sell themselves. Easy sales mean easy money.

What We Do To Help You Sell

We are starting a big advertising campaign and taking a large space in the Saturday Evening Post and the leading Trade Journals. We are furnishing real co-operation by giving you the following:—electros, window displays, folders with your name imprinted, lantern slides, etc.

These Articles Sell Rapidly

On account of the great comforts they give and because they make winter motoring a pleasure, Ieco Steer Warms and Manifold Plugs readily appeal to the motorist. Show them and they will sell. Last season although they were introduced late the Dealers who handled them were very enthusiastic.

SPECIAL OFFER
Before October 15th

In order to secure your active co-operation and have the articles in your place of business before the first ad. appears in the Saturday Evening Post, we are making a special offer to all Dealers who will buy before October 15th. This special offer means money in your pocket. **Write for full information today.**

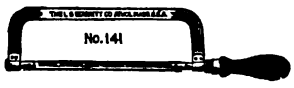
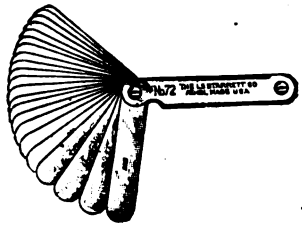
If You Own a Car You Should Own These Tools



Every man who owns a car knows the necessity for handy tools in the tool box when there is no garage nearby. For emergency repairs or for overhauling your car you will find need for all of these



Starrett Tools

They are convenient and useful. The combination square may be used as a rule, square, or level. The calipers are used in taking sizes of any part. You often need a hack saw to cut some metal part or to fit a piece for temporary repairs.

The expansion pliers are the most useful pliers made. They give the plier action on large work far beyond the reach of ordinary pliers. Their grip is extremely powerful. The thickness gage or "feelers" are useful for setting sparking points and for determining thickness of shims for loose parts.

The cut nippers are quick cutters on wire and small stock.

Send for our 320-page catalog No. 20 D. C. showing complete list of tools and prices.

Starrett Tools are sold at all good hardware stores.

THE HEISER VALVE TESTER

Shows you the leaky valves and the tight ones; it shows you the condition of the valve stem and valve stem guides. INTAKE VALVE STEMS AND VALVE STEM GUIDES worn to such an extent that they admit auxiliary air, cause erratic running motors, loss of power, waste of gasoline. It is obvious that if air passes one Intake Valve Guide that the mixture is weakened in that particular cylinder; a weak mixture pops back in the carburetor. This condition cannot be overcome by adjusting the carburetor, for it will be seen that the cylinders that are tight receive a mixture that is too rich for perfect combustion. Nine-tenths of the garages absolutely disregard the importance of this repair. Because valves have recently been ground does not indicate they are perfect. The Heiser Valve Tester verifies the work after it is done. No shop, large or small, public or private, is complete without this tester. This tester not only tests the valves of Fords but a great many others where the valve port does not exceed two inches in diameter.

The price of the Tester, delivered to any address in the United States is **$2, cash with order.** Address

Trade Mark

Patent Applied For

There was a time when water pumps at the City water stations used a fabric or leather packing; not so today. A copper jacket is put in the cylinders. Large grooves are cut in the pistons, the volumes of water in the grooves form a packing, small particles of water cannot pass the volumes of water in the grooves. Thus making a perfect packing of water against water. Just so with "NO-LEAK-O" Rings. The volumes of oil in the grooves act as a packing against the oil being drawn or forced up into the firing chamber. "NO-LEAK-O" piston rings have grooves which CONTROL THE OIL, giving perfect lubrication without waste. No smoke. No carbon. No oily spark plugs. No grinding of valves. We absolutely guarantee each ring for QUALITY, ACCURACY and SATISFACTORY service. ONE PIECE, LOW COST, HIGH EFFICIENCY. Carbon eliminated by controlling the oil. *Write at once for complete particulars.*

FRONT VIEW SIDE VIEW

THE car springs with the shock absorber attached are like a compound bow and arrow of great power. When the springs rebound there is a brake on the arrow or rod of the shock absorber, resulting in an easy upward movement. The shock absorber will outlast the car.

Simpler, more reliable than any other, requires no care. Money back guarantee. They are cheaper than car repairs, wear and tear, besides the ease of riding.

Wanted—Business-Getting Agents.

FRICTION SHOCK ABSORBER CO., Kingston, N.Y.

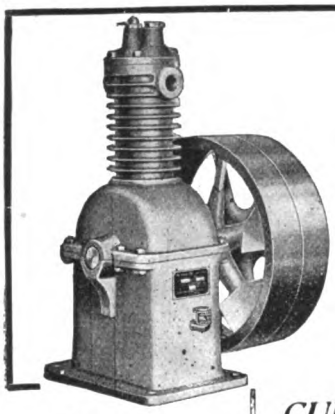
WHY REPAIRMEN SHOULD USE Marko STORAGE BATTERIES

It is an easy matter to convince Automobile owners that it is economy to use the best battery that money can buy.

Probably their previous experience with unreliable batteries will enable you to prove to their satisfaction that the "Marko" is the one they should use.

Now is the time when you should go after business.

Spring overhauling is at hand and batteries for starting and lighting purposes are an important item.



"Marko" batteries lead because of their great efficiency and reliability.

Cross head guide, Corliss engine, repaired with regular equipment at charge of $125. New casting cost $425 f. o. b. Hamilton, O. Saves 3 weeks delay.

Added profits, for live garages and repair shops

There are many welding repair jobs outside of your regular automobile repair work that you can do, with this modern welding equipment.

The welding of broken metal parts of any kind is quickly and easily done at small cost. New customers come quickly when they learn they can have their repairing done on the spot, at less cost and without the expense and delay required to replace broken parts.

Even at very moderate charges the profits are too large to overlook.

PREST-O-LITE

Dissolved Acetylene

Gives you this opportunity to increase your business

Very small outlay for apparatus is required. Equipment soon pays for itself. We furnish a thoroughly high grade welding outfit for $60. The average user will also need gas cylinders at additional cost and about $10 worth of welding supplies. Truck and special cutting equipment at extra cost. Complete instructions free with every outfit.

Prest-O-Lite Acetylene Service furnishes the highest grade of Dissolved Acetylene (ready-made carbide gas) in portable cylinders, used as conveniently as you use cylinders of oxygen. Saves the large initial outlay and heavy depreciation, trouble and inconvenience of making crude Acetylene in carbide generators. Besides, Prest-O-Lite Dissolved Acetylene is perfectly dried, cleaned and purified—makes better welds and is cheaper to use.

Start Now—Get Full Details

The demand for Oxy-Acetylene Welding Repair work is large and growing. Get your share of the profits. Send for literature that shows how you can apply Oxy-Acetylene welding in your shop, with profits to you and savings for your customers.

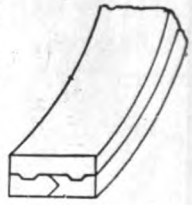
IF

one piece piston rings could exert the same pressure against the cylinder walls at every point,—

and if

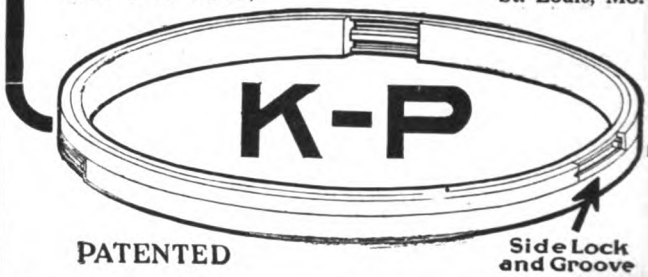


two piece piston rings, under stress, did not work "egg shaped" and "out of round"—

then three piece piston rings would not be a necessity.

But three piece piston rings are absolutely necessary to stop that costly leakage of power and compression.

"A Motor Is No Better Than Its Piston Rings."
Efficiency Ed.



K-P Piston Rings are made up of three individual interlocking rings grooved together with their section openings so distributed that multiple contact against the cylinder walls is always assured.

Honestly—what does the average man know about the Differential

He knows it's the device which makes it possible to turn a corner and that's about all. Does he know when his car is stuck in mud or sand that **it's the fault of the old style bevel gear differential, which pulls only one wheel and allows the wheel having the least traction to spin?**

Does he know that this unequal pull is the cause of **rear tires wearing out** because of "wheel spinning"? Does he know that the old type bevel gear differential is the cause of **lost traction**—and that loss of traction is the chief cause of "wheel skidding"—the start of the car skid?

M. & S. Gear Co.
Whitney Bldg.
Detroit

Without any obligation on my part, you may send me full particulars about the M. & S. Differential. I might be interested in

M&S DIFFERENTIAL

"Pulls Both Wheels"

gives you an hitherto undreamt-of control—a sense of security in driving and handling your car that is as noticeable as the flexibility between a multiple cylinder engine and a one-lunger. The M. & S. is "standard equipment" on the Jeffery Quad.

U. S. Patents 1090082
Patents in all foreign countries. All infringements will be vigorously prosecuted.

FORD Owners Get "First Chance"

The car Manufacturer can get M. & S. Differentials for equipment from the Brown-Lipe-Chapin Co. of Syracuse—the world's greatest manufacturer of differential gears.

But what about cars at present in use? We can't make M. & S. Differentials for all of them—not at present anyway. So first of all we have arranged to supply Ford owners.

Send in the coupon before you forget it and get our booklet telling all about this wonderful improvement in differential construction.

There's a great opportunity for dealers to sell M. & S. Differentials to Ford owners.

More Power For Your Car

The efficiency of your car is determined by comparing the **useful** power **delivered** to the driving wheels with that which is lost by friction. **Friction and loss of power is costly.** All of which emphasizes the vital necessity of using—

TRADE MARK REGISTERED IN

NON-FLUID OIL

UNITED STATES PATENT OFFICE

BECAUSE NON-FLUID OIL reduces friction to a minimum by providing a durable, pressure-resisting cushion between all contact surfaces. It delivers the maximum of power to the driving wheels, thereby insuring you the greatest efficiency from your car with the least loss of power and with the least wear.

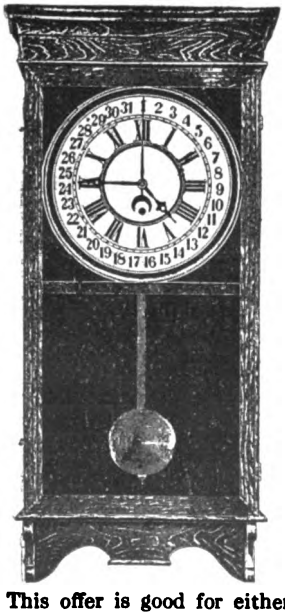
BECAUSE NON-FLUID OIL is strictly neutral—hot or cold, wet or dry, its consistency never changes. It does not leak off like LIQUID oils, nor gum up, decompose, or develop acidity and score the bearings like ordinary greases.

BECAUSE NON-FLUID OIL economizes upkeep. It lasts 3 to 4 times longer than LIQUID oils, or greases. Being of non-fluid consistency it **stays where put** and lubricates perfectly to the last small particle.

Get a can today and try it in comparison with what lubricant you now use so there can be no question of doubt as to NON-FLUID OIL'S superiority.

*The **original** NON-FLUID OIL is identified by orange-colored cans bearing the above sprocket-wheel trade mark. Avoid substitutes.*

"K No. 00 Special" grade for sliding gear transmission



"K No. 000" for differential, compression cups and all bearings

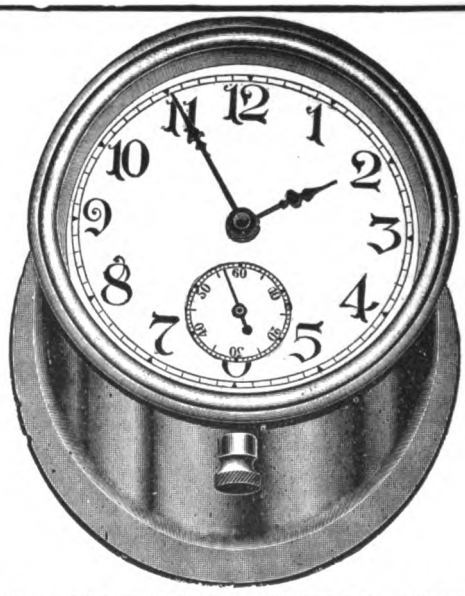
Every Repair Shop or Garage
SHOULD HAVE A CLOCK.

We have recently made very favorable arrangements with one of the largest clock companies in this country by which we are enabled to offer to our readers in the United States or its territories a **Regulator Eight Day Calendar Clock 38½ inches high, with a 12 inch dial, finished in Oak or hand-rubbed Mahogany,** with a subscription to the **Automobile Dealer and Repairer** for one year, at the very low rate of **$3.90.** This clock cannot be sent to any foreign country except Canada, and Canadian subscribers must send **50 cents** more to cover extra postage on the paper.

Every repair shop, garage or dealer's office should have one of these clocks. It will give you the time of day correctly and the day of the month.



The engraving shown gives the correct appearance of this clock.

This offer is good for either old or new subscribers.

Remittances can be made in any convenient way. Be sure to state whether you want this clock in Oak or Hand-Rubbed Mahogany.

Address all orders to

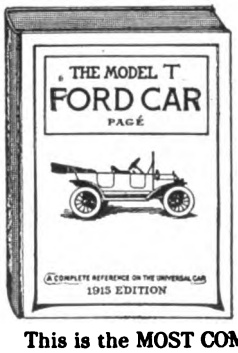
CITRUS
CUBA

Wonderfully rich land, good water, good title. Outdoor life the year 'round. A ten acre grape fruit grove will pay you $2,500 per annum for life. Eastern Cuba is to be the great winter playground of the American. The land is so fertile and accessible that fortunes are to be made in fruits and vegetables. Great country to relieve and cure rheumatism, nervous and respiratory diseases.

Present price of land $50 per acre. No frost and no irrigation or fertilization required. The young man's opportunity and the old man's paradise.

The grape fruit raised here surpasses in flavor and quality anything grown in Florida or Southern California.



The most delightful place in the world for a winter home, and very accessible. Boats sail from New York to all the principal ports, and at very reasonable rates.

For literature and further details address the

CITRUS DEVELOPMENT CO.

A NEW, COMPLETE BOOK
FOR EVERY FORD OWNER, DEALER, SALESMAN and REPAIRMAN

THE MODEL T FORD CAR
ITS CONSTRUCTION, OPERATION AND REPAIR

By VICTOR W. PAGÉ

Member of the Society of Automobile Engineers,

Author of "The Modern Gasoline Automobile," etc.

300 (5x7) Pages

Over 100 Specially Made Engravings

AND TWO LARGE FOLDING PLATES

Price $1.00

This is the MOST COMPLETE and PRACTICAL instruction book ever published on the FORD CAR. Illustrated by specially made drawings and photographs. All parts of the Ford Model T Car are described and illustrated, in a comprehensive manner—nothing is left for the reader to guess at. The construction is fully treated and OPERATING PRINCIPLES MADE CLEAR TO EVERYONE. Complete instructions for *driving* and *repairing* are given. Every detail is treated in a non-technical yet thorough manner.

Sent postage prepaid on receipt of Price

Address MOTOR VEHICLE PUBLISHING CO.,
71-73 Murray Street, NEW YORK

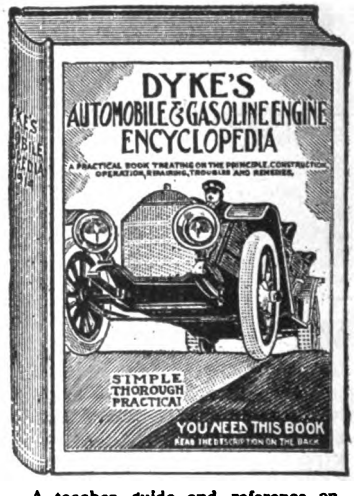
ENLARGED, REVISED EDITION
Now Ready, $3.00

(Add 25c. if wanted prepaid)

THE LATE EDITION AT LEAST ONE HUNDRED PER CENT BETTER . . .

A Complete Ford Instruction

added—as well as many other subjects. Some of the new subjects added are; **Electric Starters, Generating and Lighting Systems, up to date.**



How to Time Valves and Ignition—simplified so a ten-year-old boy can understand.

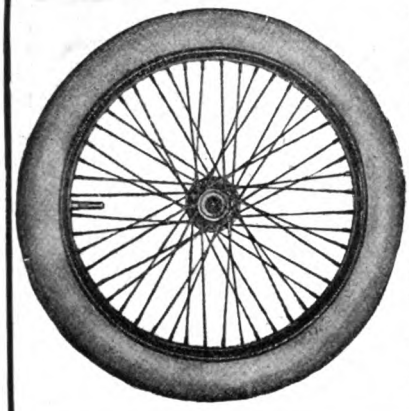
Six, Eight and Twelve Cylinder Engines; every detail from construction to firing order—simplified.

The Repair Subject—greatly improved and many new illustrations added. This subject improved at least a hundred per cent.

Complete Digest of Troubles which will make an expert of you—one capable of diagnosing troubles, scientifically—by a process of elimination—many other subjects added—such as trucks, tractors, etc.

Over one hundred thousand DYKE books sold, not one returned—yet a two-day trial examination is allowed.

A teacher, guide and reference on everything pertaining to motoring. Simple as the a, b, c's.



It's worth ten times its cost if only placed on the shelf and used as a reference when you are stuck.

Last edition, 1,000 illustrations, 596 pages. This new fourth edition, 1,750 illustrations and 640 pages.

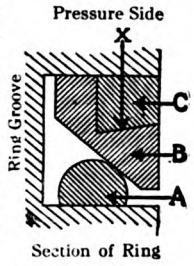
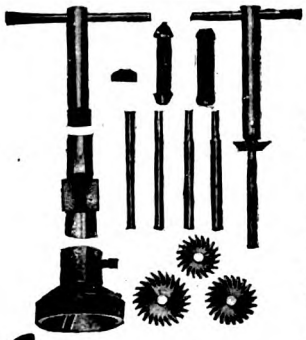
CLEAN OUT THE CARBON WITH STEAM



The Hart-Bell Carbon Remover cleans out the carbon with live steam. It is permanently installed on the intake manifold, and a turn of the handle admits a fine spray of water vapor that is instantly converted into superheated steam by the ignition in the cylinder. The steam loosens the carbon while the motor is running so that in five or ten minutes the carbon is blown out.

UTILITY PRODUCTS CO., Inc., 1414 Times Building, New York

PRESSURE PROOF PISTON RINGS



stop oil leakage because they are tight in piston groove. Study the sectional cut carefully: The spring expander A keeps the ring tight in piston groove at all times, even after groove is worn. Careful investigation has shown that oil leaks by the sides of rings, especially after they have become worn.

A Pressure Proof Ring will continue to give perfect service even if broken in several pieces. Write now for particulars concerning this interesting ring.

Section of Ring

PRESSURE PROOF PISTON RING CO.,
3368 Washington St., Jamaica Plain, Boston, Mass.

Perfect Valves—Always

Here is the tool you need to keep valves in perfect order. Regrinds and reseats in one-quarter the time needed by hand—and is 100% accurate. The

Fosnacht Valve Reseater

is simple in operation—no expert is required. No oil—no emery—no dirt—no tearing down of motor. Pays its cost in a week. Brings its owner repair work his competitor is now getting. Look into this matter *now*.

Our free book shows how the Fosnacht Valve Reseater will quickly bring you greater profits. Write for it today—while you think of it. Address

Suite 795 30 No. Michigan Boulevard
CHICAGO, ILL.

BROWN SUB-BASE OILER
FOR FORD CARS

PAT. DEC. 8, 1914

The hit of the season. 450 miles on a filling of oil. No pump or sight feed drips—entirely automatic. Can be attached in 15 minutes—no holes to drill. 75 degrees difference in temperature of oil. Less oil and carbon. Cannot flood the motor. Send for booklet on proper lubrication.

Price, ready to attach, $6.00

THE BROWN CO., 100 Bellevue, SYRACUSE, N. Y.

ONLY CLEANER THAT REALLY CLEANS

For driving safely when the windshield is up, in summer showers or winter storms, an OutlooK Cleaner is absolutely needed. A simple accident costs many times as much as the Cleaner, to say nothing of the comfort, convenience and peace of mind.

OutlooK Cleaners fit any windshield, have an adjustable wiper, black or nickel finish, best grade of rubber used. Attached in two minutes.

Retail Price, $1.50.

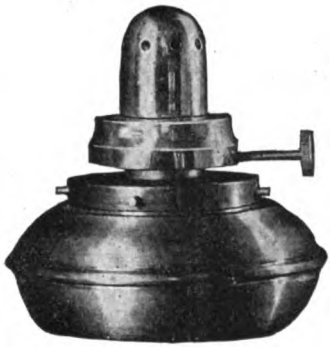
Station B, Box 124, CLEVELAND, OHIO.

Repair Gum

Car owners and chauffeurs find Goodyear repair gums, fabrics and cement, all cure in the same time and pressure. This is the convenient combination for satisfactory and quick repair work.

Goodyear Gums are uniform. You get the exact gauge you order. The standard for tube stocks is 1-32, for tread stocks 1-16 inch. The rolls are 18 inches wide. Goodyear Gums are practical and efficient. The line is complete—tread gums, tube gums, cushion gums and cement stocks varying in color, cure and weight.



Investigate the Goodyear line of Tire Accessories. Each will save you extra tire mileage if applied before complete ruin of casing or tube has taken place. Write for this list with "Emergency Repair Book." Address Desk 154.

EVENLITE
for FORD CARS
Constant Even Light at 6 Miles or 60

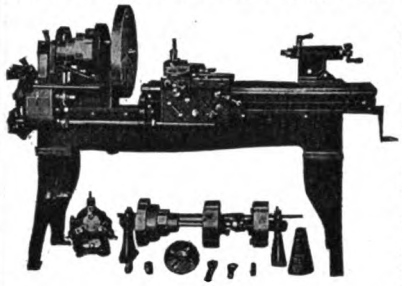
The Evenlite affords a full, clear light at 6 or 7 miles which is as slow as the car can be run in high. It gives as good a light as a battery system and requires no attention whatsoever.

The Evenlite is a special type impedance coil which equalizes the flow of current, thereby keeping the lights constant at all speeds. The Evenlite consumes only one-half the energy that the standard Ford lighting system consumes from the magneto.

The Evenlite saves 50% of the current and as a result an electric horn may be operated without robbing the spark or weakening the magneto.

On Approval—Our Risk

We want every dealer to see an Evenlite at work, and will ship subject to your fullest approval. You can install in 15 minutes—very simple.



Evenlite with lamps - - $3.50
Evenlite without lamps - 3.00

Discount to trade.

A POWERFUL LIGHT AT LOWEST ENGINE SPEED

The Price is But
$5.00
Complete

You have nothing else to buy

The season has arrived when satisfactory lighting is an absolute necessity. Therefore if your Ford car is not already equipped with the **NEW YORK ELECTRIC AUTOMATIC HEAD LIGHT CONTROLLER,** you should purchase at once if you desire to have a light as powerful at low speed as the best storage battery-dynamo system.

Our device makes use of the Ford fly wheel magneto and gives an equally efficient light at the highest as well as the lowest speeds at which the car can be run. At the same time it prevents the bulbs from becoming burnt out. **The value of this system is so great** that you simply **cannot afford** to be another day without one.

Do not compare this instrument with so-called transformers, resistance coils, etc. It is in use at this minute on thousands of Ford cars and stands **unquestioned as the first and only practical solution to the electric light problem on Ford cars.** You can install it in ten minutes. *Absolutely Guaranteed.*

We also manufacture the famous New York Master Vibrators, UNI-Coil Ignition Systems, Rhoades Battery Ignition System, and other **high grade** accessories for Ford cars.

Send for our booklet, "FORD PROBLEMS EXPLAINED."

Two Ignition Systems for Ford Cars

The New York UNI-Coil Ignition System for Ford Cars

PRICE $15.00

Operated by the Ford Fly Wheel Magneto (or Battery)

This system is primarily intended to operate on the Ford fly wheel magneto. It consists of a well-made elevating rear bracket upon which our Combined Timer and high tension Distributor is mounted. The Distributor is of the most simple construction containing the essentials of the high tension magneto. It uses one unit equipped with vibrator of your regular Ford coil. It dispenses with the timer and practically all of your present wiring, insuring a perfect timed spark and freedom from trouble.

The only satisfactory distributor system for the Ford magneto.

Furnished complete to the smallest detail.

Rhoades Non-Vibrating Coil

The Rhoades Battery Ignition System

is intended for the class of Ford owners who prefer to **dispense entirely with vibrators.** This system operates entirely on battery, six dry cells supply ignition for from two to four thousand miles. **We supply a handsome non-vibrating coil fitted with kick switch,** also elevating gear bracket. Six years of hard service have proven it to be the best battery system obtainable for Ford cars.

PRICE $20.00

RHOADES UNIT SPARK SYSTEM

Prevent your Ford from being stolen by buying

Our New York Kick Switch With Yale Lock--Price $2.50

which fits the new Ford metal or wood coil boxes. This is a handsomely constructed **kick switch containing a genuine Yale Lock,** which affords the convenience of the regular Kick Switch, but possesses the locking feature which is found in no other type.

Anyone can install—Remit $2.50 today—Money back if not satisfactory

INSTALL A GENUINE

New York Master Vibrator on Your Ford Car

Price $8.00 at Your Dealer's
and enjoy the smooth, evenly applied power so noticeable in six-cylinder engines

It is immaterial if your car is the latest or oldest model. You need our master vibrator, as it dispenses with all coil adjustments and replacements, and insures easy starting, a hot, perfectly timed spark under all conditions, and entire freedom from ignition troubles. It has for the past six years proven itself to be superior to any existing type. Though many times imitated it has never been equalled and stands today the best in its class at any price.

With fittings to install on the new 1916 models

Our Booklet, answering many questions that have puzzled you, is free for the asking

A Great Conference Of Interest to All Tire Users And Dealers

Once every year all Firestone salesmen meet at our Akron headquarters.

At our first annual meeting only thirty men were present; this year, September 28th, 29th and 30th, over three hundred were present from all parts of the United States and several foreign countries.

Besides attending the general sessions addressed by the Company executives, branch managers and salesmen, every representative spent hours in the factory studying, in a practical way, the manufacture of Firestone tires. They saw Firestone experts building in the "extras" you have been reading and hearing about; that extra layer of fabric in the five-inch tire; the extra ply in the three-inch; the extra coating of pure gum between the plies, etc. They saw the "inside" reasons why 50 per cent more Firestone dealers were added last year, and why our output was increased 78 per cent.

They saw five great buildings under construction to provide over seven acres of additional floor space which will increase the Firestone output of pneumatic tires from 7,500 to 12,000 a day. This increase of 4,500 tires per day is larger than the output of the original new Firestone plant erected on its present site four years ago.

They rubbed shoulders with hundreds of men whose interests are kin to theirs, and from them they reaped a great harvest of valuable and helpful information which they will use to the advantage of customers.

These days of conference and study represented a large investment, but it will produce adequate dividends in better service for tire users the world over. It will mean a greater, more alert, better informed Firestone organization, and that insures satisfied customers. And there you have the vital reason for it all because—satisfied customers constitute the corner stone of the Firestone business.

Fifty dollars in the road —Would You Stop to Pick It Up?

The motorist who throws away his half worn tires without having them re-soled by the European method is doing the same thing as though he saw from $50 to $200 lying in the road, but drove on without stopping.

Your Half Worn Tires Are Still Good for 5000 Miles

For over three years European motorists have been getting from 10,000 to 15,000 miles out of their tires by "half-soling" them with Steel Studded Treads, just as we half-sole our shoes when the original sole gets thin.

In eight months over 20,000 American motorists have followed their example and are saving $50.00 to $200.00 a year in tire expense. And what is just as important, they have almost entirely eliminated the constant dread of punctures, rim cutting and blowouts!

Guaranteed 5,000 Miles Without Puncture

Think of it—a 5,000 mile tire vacation—to be able to FORGET tires!

This is a pretty strong statement unsupported, but it's not merely a claim.

Durable Treads are delivered to you under a signed guarantee for 5,000 miles of wear without puncture.

This guarantee is an ironclad agreement—as good as a government bond—and holds good whether your tires are new or old, tread worn, rut worn or rim cut.

Durable Treads cover the tire completely, extending entirely around from rim to rim. Nothing can work its way in between. They afford a perfect protection—that's why we can guarantee them as we do.

No More Skidding

Durable Treads are studded with sharp-edged steel rivets which dig right down through the mud and slush and get to earth every time. In London and Berlin, as well as many other of the larger cities of Europe, ordinances compel the use of steel studded Treads for public safety.

Durable Treads are always on your tires—you don't need to worry about climbing out in the rain and mud to adjust your chains—and what is more important—you receive perfect non-skid service while your tires are protected instead of injured.

Special Discount Offer

To motorists in territories where Durable Treads are not as yet represented we offer a special introductory discount for advertising purposes equal to the full dealer's profit. This offer is limited, however, and may be withdrawn at any time.

We Ship On Approval

You have everything to gain and absolutely nothing to lose, for all we ask is the opportunity to give you a demonstration at our own expense and risk.

We have a catalog, sample and copy of written guarantee ready to send, and they're yours free for the asking.

Don't let the tires on your car run another week in "bare-footed" condition—don't wait until you get your next puncture or blow-out.

Fill out and mail the coupon right now and you will hear from us within a week; no expense and no obligation to you.

Better Business in Slack Seasons

Last month we told you of our plan to get car owners interested in winter driving. We are keeping right on with our talks to Mr. Owner about putting his car in shape—**now**—before the bad weather comes.

He's willing enough to keep his car in use if he sees any possible way to protect himself against power failure and those other troubles and inconveniences he has always connected with winter driving.

So we're doing the telling—and it's up to you to do the selling on

LEAK-PROOF Piston Rings

MADE BY McQUAY-NORRIS MFG. CO

Back up our advertising with your own personal effort on your customers. Get them to see there is right and reason in our arguments. You know the LEAK-PROOF Ring and what its performance record is; you can bank on it making good with every car owner who tries it.

You can make a good season of the dull Fall months by supporting this "Install LEAK-PROOF Piston Rings for Winter Use" idea. Last year lots of dealers found it a profitable idea to push—and—remember, every owner who isn't using LEAK-PROOF Rings now is a prospect for you because he will be looking around for them sooner or later.

And, remember too, that there are imitations and substitutes masquerading as LEAK-PROOF Rings. Use the patented angle-to-angle interlocking construction of the two members of the genuine LEAK-PROOF Ring to identify it. Look for the name stamped on the Ring.

Write for FREE Booklet, "To Have and To Hold Power."
Explains LEAK-PROOF construction—gives you facts and arguments that will sell your customers on LEAK-PROOF RINGS.

"Ask the User"

Angle-to-Angle interlocking construction identifies LEAK-PROOF —insist

The Ford is not Responsible for Rough Roads

But no matter how rough the roads or how fast you drive you can ride smoothly over every inch of the roughest roads when you equip your Ford car with

TRADE K-W MARK REG U.S.PAT OFF **Road Smoothers**

QUICKLY APPLIED TO YOUR FORD CAR

Give your Ford car advantages, with heavy car comfort

In Buying, Here's What You Must Look For in Order to Combine Comfort, Safety and Economy:

1. A spring to effectively take up the shock.
2. An Anti-rebound air chamber to check the rebound.
3. Anti-side motion links to prevent side rocking and swaying.
4. **A construction that absolutely does *not* interfere with the steering.**

Each of these features is in itself vital to your comfort and safety. It's only when they are combined in one device that you will get the greatest pleasure from your car. Here's how the K-W Road Smoother fills all these requirements:

The K-W Spring

A helical spring that effectively takes up the shock, made of electric smelted, chrome vanadium steel. The K-W bracket design allows almost *twice the length of spring action* or "travel" (in actual service) of any other.

The K-W Air Chamber

The anti-rebound air chamber with its smooth fitting piston acts like a door check, and gently "eases off" the rebound of the spring. This is an exclusive K-W feature. Its design provides a strong, tough, self-lubricating piston, working in a dust-proof air chamber. It requires no attention.

The K-W Side Motion Links

Made of the highest grade heat-treated drop forgings of remarkable toughness. This enables them to withstand the great strain put upon them. They prevent your car from pitching, swaying or skidding while making sharp turns.

$15 SET OF FOUR
ONE FOR EACH WHEEL

K-W Road Smoothers absolutely do *not* interfere with the steering.

K-W Bushings

All bearings are phosphor bronze throughout. That means long life.

But you can find all of these vital factors only in K-W Road Smoothers!

That is why they lengthen the life of your car, by eliminating shock and vibration. Tire economy is assured, because K-W Road Smoothers enable the wheels (not the whole body of the car) to follow the contour of the road. That means no grinding off the rubber of the tires. K-W Road Smoothers always make good because they are built with characteristic K-W quality throughout.

But after all's been said and done it's results that count; and the K-W guarantee covers not only workmanship and material, but *results* as well.

K-W Road Smoothers are quickly and easily attached. No holes to drill and no tools necessary, except a wrench. And the final and biggest advantage you get from K-W Road Smoothers is that they increase the radius of your car's usefulness, and bring you home with "that satisfied feeling" after a day of comfortable motoring.

If your dealer can't supply you, sent prepaid upon receipt of price.

Write for booklet, "That Satisfied Feeling."

WATERHOUSE COMPLETE WELDING OUTFIT Costing Only $42

Free Trial allowed at that.

Repair and Garage men can add considerable to their income and make up for losses in other ways with money made with one of our outfits.

The equipment necessary to weld with our outfit is so small and compact, it occupies very little space.

You can also save considerable money for your customer, as well as making money for yourself.

The Waterhouse Outfit

	Value
1 B Welding Torch with 5 tips	$17.00
1 Oxygen Reducing Valve with 50 lb. line pressure gauge	10.25
1 Acetylene Reducing Valve with 50 lb. line pressure gauge	11.00
1 Set of Special Welding Hose (20 ft.)	3.00
1 Pair of Welding Glasses	.75
1 Carbon Burning Torch	Free
1 Set Instructions	Free
Net Cost Complete	**$42.00**

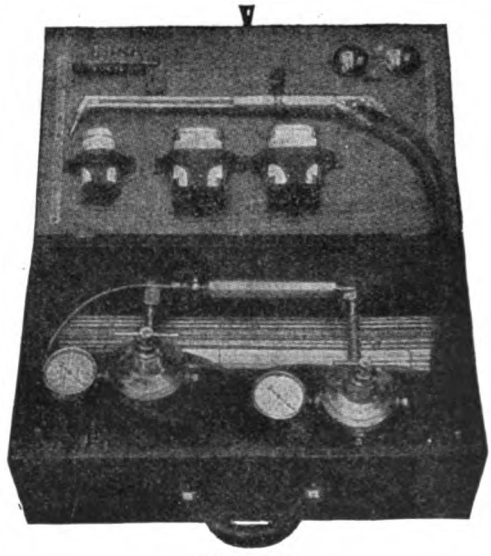
If you have a regulator for carbon burning, the oxygen regulator with the outfit is unnecessary, and you can deduct the price ($10.25), from the above total price.

TERMS: 5% discount cash with order or C. O. D., or $20.00 cash with order, balance in two payments, first of $12 in 30 days, $10 in 60 days.

ABOUT TANKS

The two gases used are oxygen and acetylene. The regular automobile lighting cylinders contain acetylene, so you can use them, and oxygen can be bought in loaned cylinders at little cost.

If supplies are desired as well, we will sell for $4.50 additional the following, making you ready for any auto welding:



1 Bottle Aluminum Flax
1 Can Cast Iron Flux
1 Can Copper and Brass Flux
5 pounds Cast Iron Welding Rods
2 pounds Aluminum Welding Rods
2 pounds of Steel Welding Rods
2 pounds Brass Welding Rods

Send at once for descriptive circular.

The Smartest Accessory you can put on your Motor Car

A welcome achievement has been worked out for the interior trim of motor cars—Campbell Detachable Upholstery.

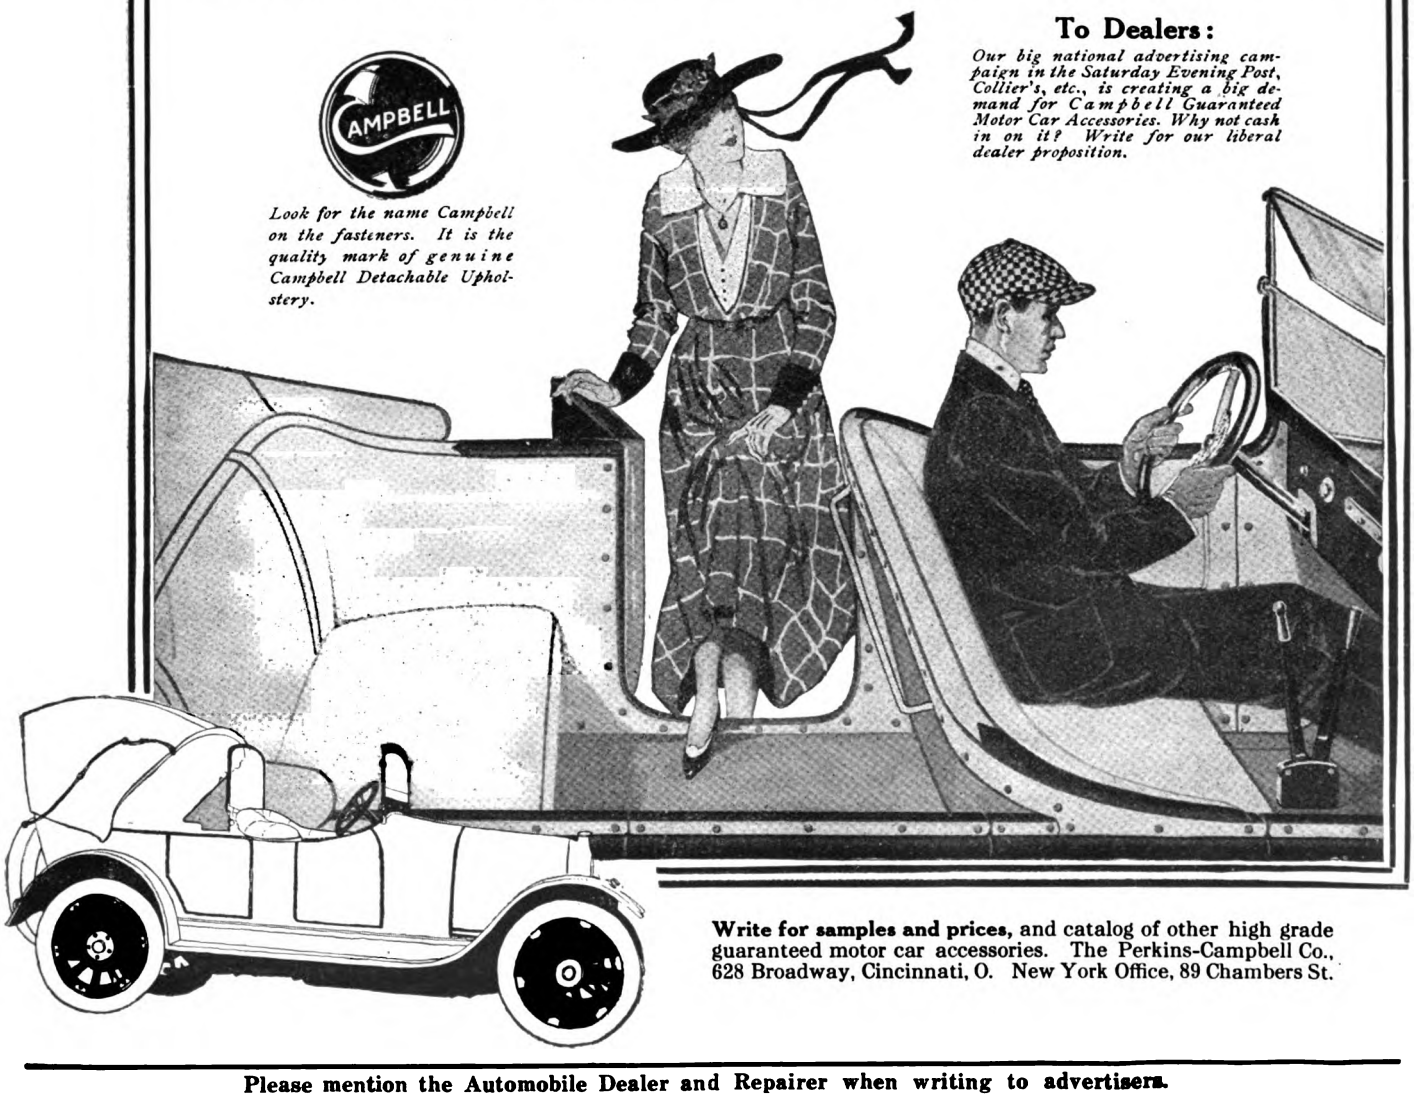
It transforms the car with the shabbiest upholstery into a car of luxurious beauty. To the new car it adds a touch of smartness that no other single unit of equipment can give it. It is Full Dress for Motor Cars!

CAMPBELL ESTABLISHED 1879 **DETACHABLE UPHOLSTERY**

Anyone can install Campbell Detachable Upholstery in a short time. It is hand-tailored to fit over the regular upholstery of your car without alterations, and is held by quick-detachable fasteners. In appearance it is an inherent part of the car, not a mere attachment, yet it can be removed for cleaning and replaced in a few minutes.

Many new fabrics

Campbell Detachable Upholstery is made in many beautiful, rich tones of special motor cloths and linens. It permits of an interior trim that is a harmonious part of the general color scheme of the car. It combines the smart luxury of the finest limousine trimmings with the durability of good leather. It affords greater comfort and cleanliness.

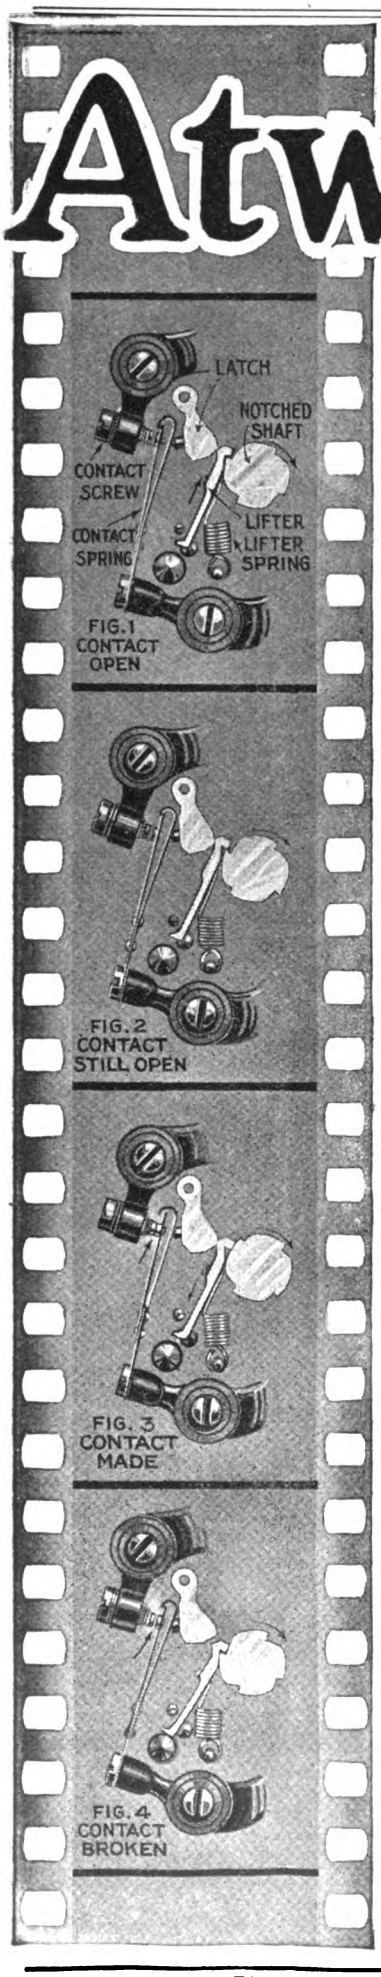


If you contemplate buying a new car, ask to have it fitted with this stylish equipment. Or, if you already own a car, no matter how old it is, you can freshen it up with Campbell Detachable Upholstery in just the fabric and shade that best suits your purse and your taste.

To Dealers:

Our big national advertising campaign in the Saturday Evening Post, Collier's, etc., is creating a big demand for Campbell Guaranteed Motor Car Accessories. Why not cash in on it? Write for our liberal dealer proposition.

CAMPBELL



Look for the name Campbell on the fasteners. It is the quality mark of genuine Campbell Detachable Upholstery.

Write for samples and prices, and catalog of other high grade guaranteed motor car accessories. The Perkins-Campbell Co., 628 Broadway, Cincinnati, O. New York Office, 89 Chambers St.

Atwater Kent Ignition

The lifter as it is pulled forward by the notched shaft does not touch the latch, and the contact points remain open.

The lifter, reaching the point where it rolls off the notched shaft is pulled back by the lifter spring, striking the latch as it returns.

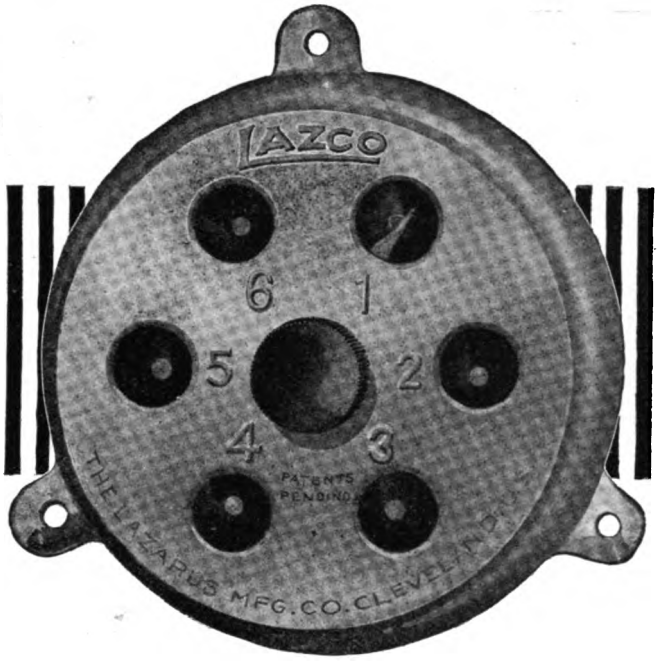
The latch, being struck by the lifter, presses against the contact spring and closes the contact points for a brief instant, immediately opening after the lifter passes.

The latch and lifter, having returned to their original position, are ready for the next spark.

Owing to the fact that it is impossible to stop the motor in any position which will leave the ignition circuit closed, the Atwater Kent System is fundamentally safe, and no accessory safety devices are necessary to protect the battery. The current flows only during the brief instant of each spark and the ignition switch is practically useless except for stopping the car. In other words, it might be left in the "ON" position permanently without the slightest danger of draining the batteries.

The Atwater Kent principle is absolutely unique among ignition devices. Its success is certified by more than nine years of uninterrupted growth. It is in use to-day on upwards of 200,000 cars and is endorsed by more than 30 reputable manufacturers and over 10,000 dealers, garages and repairmen.

The Atwater Kent magneto replacement system can be easily installed in place of the magneto on any standard car. Thousands upon thousands of car owners realizing the benefits of Atwater Kent Ignition are installing this system on cars previously equipped with magnetos and other types of ignition.



Our special outfit for Fords deserves the investigation of every owner of this remarkable car, and the opportunities which it offers to dealers, garages and repairmen are attracting the attention of the entire trade.

If you are a car manufacturer, dealer or owner and are not fully posted regarding this wonderful system, by all means get in touch with us without further delay. You owe it to yourself to have our complete data on file.

LAZCO LAZCO

American and Foreign Patents Pending

Dial Actual Size

Engine Trouble Detector

"More necessary than the speedometer, more useful than the clock"

Fulfills a positive need in the convenience and economy of motoring. With the Lazco Detector you can quickly locate and determine engine trouble from the dash, without raising the hood. Misfiring cylinders, carbonized or broken spark plugs, faulty ignition, cylinder knocks, battery and magneto difficulties, loose connections, lack of compression, etc., are simply and conveniently investigated and determined with the aid of this ingenious device. No complicated connections. You can install it yourself. The dial is quickly attached to the dash—boring one ¾" hole through which to pass the motor connections. The ONLY DEVICE of its kind and purpose. No motorist can afford to be without one. Shipped complete with all attachments and instructions.

SELL the only BUMPER that can be struck without being damaged!

PATENTED

There are Bumpers galore—but only one that really protects and which won't break. The others are all alike. Their claims are strong—but their action mightily inefficient. The

LYON Resilient Bumper

is different. You can run it into a pole at reasonable speed without injuring either the bumper or car! Strong statement? Prove it yourself at our expense.

The LYON is resilient, having ten times as much spring play as any other make.

The LYON is clamped on any car in 15 minutes; harmonizes with streamline bodies and is guaranteed not to rattle or become loose. It is packed in individual boxes, making it easy to reship. The price is low.

$7.50 up to $10.50; all finishes. FORD Bumpers $6.00

Why sell others that cost as much or more and don't deliver the goods? Give your customers their money's worth by selling them the LYON. We have something interesting to say to dealers and garagemen. ***Write us at once.***

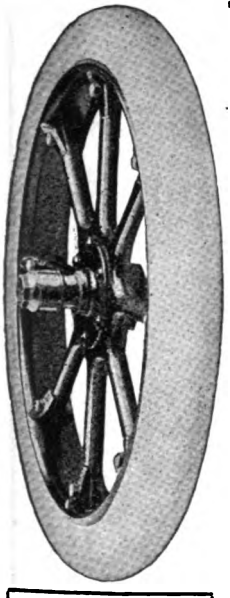
It's High Time To Heat Your Garage

Now, during the early days of autumn is garage heater time.
Every man who owns an automobile faces this problem annually.
What provision have *you* made against cold weather deterioration?

THE FAMOUS 1916 SCIENTIFIC SAFETY GARAGE HEATER

The famous Scientific Safety Garage Heater is now ready for immediate delivery. Over 5,000 of these heaters are giving satisfactory use all over the world. The only heater listed by Underwriters. Cannot explode. Economically consumes artificial or natural gas. Simple to install. Easy to operate—no matches required. A self-lighting device eliminates danger from an exposed flame. Hot water always handy for washing the car.



This compact heating system occupies what would otherwise be waste room. Built in three sizes. The No. 700 size will comfortably heat the ordinary two machine garage during zero weather. The price of this model is $25.00.

Use Your Car in Winter

By using the Scientific Safety Garage Heater you can start your car in January as easily as in June. There is no danger from frozen radiators or cracked cylinders. Parts cannot rust or gum. Batteries take full charge. Truck deliveries are made efficient.

Ask your dealer first or write today and secure a free copy of "Scientific Garage Heating."

2300 Power Ave. Cleveland, Ohio

$19.75
SET OF FOUR
Enameled black, 30x3½" wheels; spare clincher rim; full set new hub bolts and brace wrench. With wheels enameled red and clincher rim enameled black, $20.50.

Stop Carrying Around 192 Pounds of dead weight!

Any automobile engineer will tell you that a pound of weight under the springs is equivalent to six pounds over them at ordinary speed.

PARKER-HYDRAULIC
PRESSED STEEL WHEELS FOR FORDS

weigh 32 pounds ***less*** per set than wooden wheels with demountable rims. This is equivalent to a 192-pound load—the weight of a big man.

This decrease in unsprung weight means more mileage from your tires and quicker acceleration. Altho lighter, these wheels have such remarkable strength that they are practically unbreakable, and if bent by some terrific strain that would smash any other wheel, they can be easily straightened. Your safety is assured.

They give you the simplest and quickest demountable rims—the only part to come off being the rim itself—no loose parts—nothing to stick.

These wheels have a handsome baked-on finish, are easily cleaned and non-rustable. They combine strength with their light weight and allow quick tire changes.

Sold by reliable dealers everywhere. If you don't know yours, write us.

These wheels offer a real opportunity to live dealers. Full details on request.

A Magic Wand

For the Modern Garage

THE Searchlight Oxy-Acetylene Welder is the magic wand of the modern garage. With it enormous profits can be made.

The work your competitor can't handle, is the work which makes you your biggest money.

You'll find no end of profitable work for a Searchlight Welder.

You will be able to repair broken castings and auto parts easily, quickly and cheaply, getting a long price because of the strength and neatness of the job and because of the time saved for the delayed tourist.

You will also be able to build up a very profitable general repair business for the factories in your neighborhood.

Broken castings which tie up factory machinery often cost hundreds of dollars and profits lost. No process or method of repair (or even of replacement) can compete with Acetylene welder. It is easily portable. You can carry it right to the job. You make repairs without even dismantling the machine. Guarantee a quick job and quote a price which allows you an unusually large profit. You will get it every time.

Searchlight Welder

This is the only welder in its class which sells for less than $100. Our price for complete equipment is only $50.00 (cylinders extra, however).

Write for complete information and we will show you the new source of big profit.

A Great Victory--Science Conquers!

The Gemco Steam Vaporizer

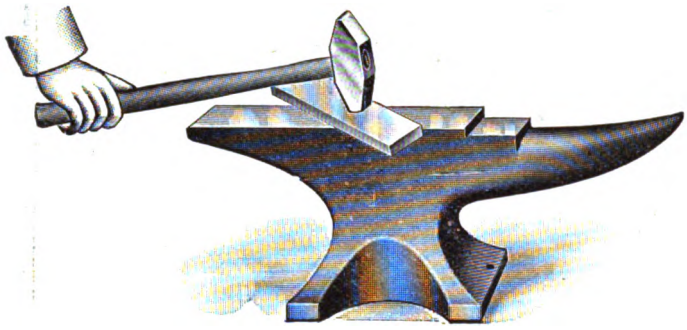
Kills Carbon

Gemco MILWAUKEE "THE SIGN OF SATISFACTION"

MORE POWER AND A CLEAN MOTOR are the two most important results achieved by the "Gemco" Steam Vaporizer. Works absolutely **AUTOMATIC**—requires **NO ATTENTION**—mechanically perfected—operates as a part of the motor and at **NO COST.**

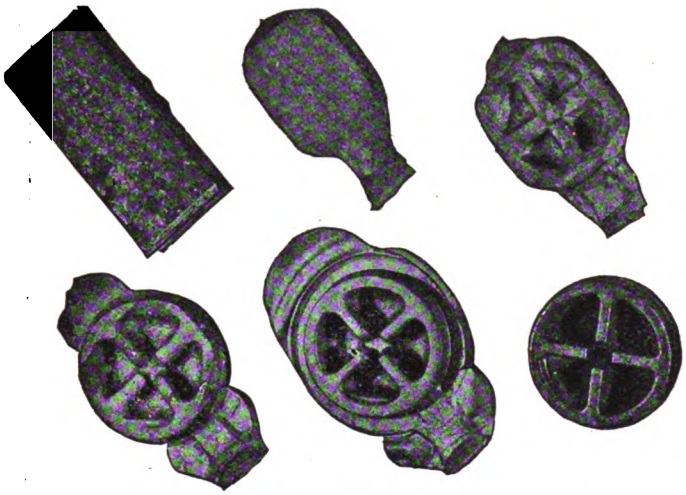
THE PRINCIPLE IS the suction of water from the cooling system converted into steam and injected into the firing chamber. The moisture loosens all carbon, assists more perfect combustion and eliminates new carbon deposits which means less fuel and a smooth-running Motor.

THE MOST IMPORTANT INVENTION IN MOTORDOM. It solves the greatest problem—Carbon—that the motorist has had to contend with.



Remember Gemco Guarantees It

Quickly attached without mechanical changes. Packed in a neat carton with directions; three sizes:



No. 1—Ford Special	$5.00
No. 2—For 1½ and 2 in. dia. exhaust pipe	6.00
No. 3—For 2½ and over dia. exhaust pipe	6.00

Patent Applied For

The Most Perfect Piston Rings Made

PERFECTION PISTON RINGS

They are made of soft, elastic steel in sections 1/16" wide and one section is required for each sixteenth in width of the groove. They give compression and power to your motor unequalled by any other rings. They present a barrier to the gas in the combustion chamber such as cannot be possible with a one piece ring.

This construction gives perfect compression, maximum power, minimum carbon, smaller oil consumption, lower gasoline bills, less smoke, and saving in repair bills. These rings are put on the pistons without being stretched, and this is impossible with one piece rings, which are always distorted when stretched over the pistons.

PERFECTION PISTON RINGS are made in all sizes and can be sold by dealers to great advantage. *Let us give you special quotations for your requirements.*

What stopped the automobile in front of your door?

Brake Lining!

There is a constant demand from motor car owners for brake lining, because even the best will not last forever. There is a steady demand for

Thermoid HYDRAULIC COMPRESSED Brake Lining - 100%

because it is known universally as the brake lining that retains its gripping efficiency until worn paper thin. Thermoid is brake lining clean through—tougher for its purpose than steel itself. It is brought by hydraulic compression to a uniformity and density that give 100% gripping power until it is actually worn out. Even that takes months longer.

You will find it worth your while to look into Thermoid as a motor accessory staple. A line will bring further particulars.

For Leaky Cylinders

Superior to All Others

EVER TIGHT

PATENTED AUGUST 6, 1912

A Piston Ring Which Gives Compression in "Out-of-Round" Cylinders as Perfectly as in True Ones

Beware the "Just as Good"

Here is a piston ring that gives 100% efficiency to every type of motor, engine, compressor or pump.

Ideally adapted to use in Automobile and Motorboat engines.

Gives compression when all others fail. No need to rebore worn cylinders—simply install EVER-TIGHT piston rings and the motor is good as new.

EVER-TIGHT piston rings are made up of three individual, interlocking rings, grooved together to give flexibility and reduce friction. This three-part construction is clearly seen in illustrations above. This is the only three-piece piston ring on the market.

If dealers do not carry EVER-TIGHT piston rings, Auto repair men should write us.

Jobbers and dealers wanted everywhere. *Write for particulars.*

THE EVER-TIGHT PISTON RING CO.

1428 CHESTNUT STREET ST. LOUIS, MO.

The Foundation of this Tire

is just as good as the day it was bought. Any tire with good fabric, whether there is any rubber on the outside or not, is suitable for the

TRIPLE TREAD PROCESS

The Triple Tread is the only tire protector made

that does not depend on inflation, rim pressure or mechanical means to hold it in place, so that the style of bead on your tires cannot affect the success of their treatment.

In Vulcanizing the Triple Tread on your Tire

we are able to fill the pores of the leather with rubber, making it waterproof, so that by bringing the leather down the sides and over the bead of the case, covering it completely, we are able to keep dirt and water from getting under the tread to rot the fabric, and also to strengthen the sides and bead of the tire.

Write for our booklet,

"Worn Out Tires Made New."

Please mention the size of your tires.

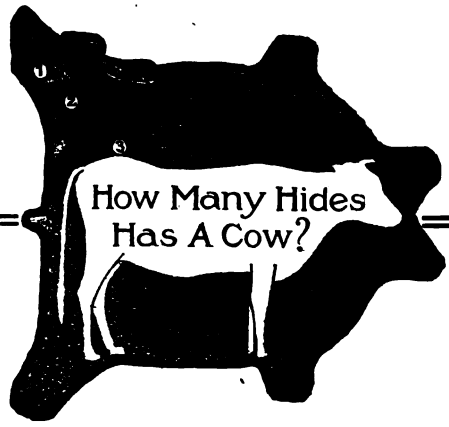
Full length doors operate with one handle. Generous over hang in front accentuates the length of the Ford.

Mandel TRADE MARK Limosette

See the Mandel Limosette at Local Dealers.

Built exclusively for 1913-14-15 Ford Cars. Can be attached in less than an hour. Adds about 40 lbs. to weight of Roadster. 75 lbs. to Touring Car.



Gives Ford owners the luxurious convenience of a modern, high priced limousine at a very small investment.

Write for Illustrated Book—Free

MANDEL LIMOUSINE COMPANY,

1453-1455 Congress Street, Chicago, Ill.

IF all the cowhide used for upholstery purposes were real grain leather, the answer to this unusual question would be easy. Also the life, wear and service of most automobile and furniture upholstery would be longer. But such is not the case.

Only one-third of this cowhide is genuine grain leather. The remaining two-thirds are "splits"—weak underlayers of hide dyed, coated and embossed to look like the genuine article and sold as genuine grain leather. But they give neither its wear nor service.

The Ideal Upholstery Material

DU PONT FABRIKOID

REG. U. S. PAT. OFF.

Guaranteed Superior to Coated Splits

is not leather, yet has the luxuriant appearance and feel of the finest grain or Spanish leather. It is water, dust and grease proof and twice as strong as coated splits. It is guaranteed for one year, but built to last for many. And back of this sincere guarantee stands the century-old Du Pont reputation for integrity of purpose, superiority of product and financial responsibility.

If you want upholstery satisfaction, insist upon Motor Quality Fabrikoid for your automobile and Craftsman Quality for furniture. Fabrikoid Rayntite, both single and double texture, guaranteed not to leak for one year, makes the finest tops for both automobiles and buggies.

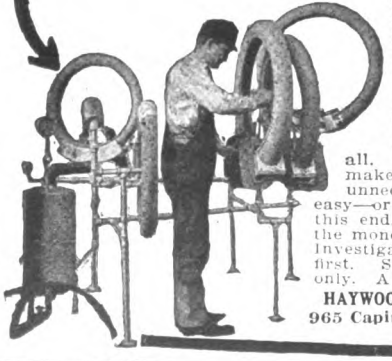
Add $250.00 A MONTH EXTRA To Your Business



REPAIR AUTOMOBILE TIRES

Sounds like a whole lot of money to clear extra every month. Seems almost impossible, but that is what hundreds of men are doing who have added a Tire Repair Department to their business. **The investment is small, the profit large** and **returns quick and all cash**, besides the demand for tire repairing and retreading is constantly growing. Your garage is by no means complete, your business is not as profitable as it can be until you get in on the Tire Repairing and Vulcanizing end.

THE HAYWOOD TIRE REPAIR EQUIPMENT

Answers all the requirements to successfully handle this end of the business. With it and a little business judgment, success is certain. Every year adds thousands of new auto owners. They are looking more and more to economical tire service. The day of discarded tires is over, the Haywood Equipment makes this possible.

HERE IS YOUR OPPORTUNITY

Either as a side line to your present automobile business or as a business by itself, the Haywood Equipment will make money for you. **Tires go wrong all the time.** You know that. Keep them in tune. Give your customers complete service—repair their tires and all. This builds business and makes you rich. Experience unnecessary. You can learn easy—or teach a boy to handle this end. Be the boss and make the money. Learn the details now. Investigate. Act quick. Be the first. Send name and address only. A postal will do.

HAYWOOD TIRE & EQUIPMENT CO.
965 Capitol Ave., Indianapolis, Ind.

STA-TITE

There's Good Profit for Dealers Who Sell

STA-TITE PISTON RINGS

"Power to Burn—Without Waste"

They so increase the speed and power of a motor and are so economical that every user is delighted and soon sends his friends into your store for some of these wonderful STA-TITE Rings.

Made in three sections—two outer rings fitting over an inner ring—they effectually prevent loss of compression, and by keeping oil from the combustion chamber, stop waste, excessive formation of carbon and smoking.

STA-TITE Rings fit perfectly, last indefinitely, and are fully guaranteed. They sell fast because they are the best rings to be had, increase power and save money.

We also make "Quality" snap rings— cast individually—the best ordinary piston rings to be had. All sizes carried in stock.

Get our dealers' price—it means good profit for you.

"NORMA"

BALL BEARINGS

Can you afford to set up your opinion as a small user of bearings, against the judgment of the makers of high-grade magnetos, lighting generators and starting motors who use bearings by hundreds of thousands? These makers use "NORMA" Ball Bearings in their machines. Isn't this the best of reasons why you should do the same? How about a small stock of "NORMA" Bearings, in the common sizes?

THE NORMA COMPANY OF AMERICA

1790 BROADWAY NEW YORK

"NORMA"

MORE POWER GREATER MILEAGE

Show your patrons how to get full power in cold weather! Help them to avoid fuel waste and reduce carbon deposits by making combustion quicker.

Single Plug ignition won't do it. **Two Plug ignition will!** By starting the flame from **two points at once**, it makes combustion almost instantaneous.

A wonderful increase in power and mileage comes of using one

SU-DIG SERIES PLUG

per cylinder in connection with the regular plug. Spark manipulation is reduced, and leaner mixtures successfully burned.

No change is needed in magneto or battery system. Tap the valve caps if necessary.

Our national advertising is creating a demand. Write today for valuable dealer helps.

WONDER-MIST

Cleans and Polishes

It removes dust and stains and restores the original lustre to any polished surface.

It contains neither acid, gum nor any other injurious substance.

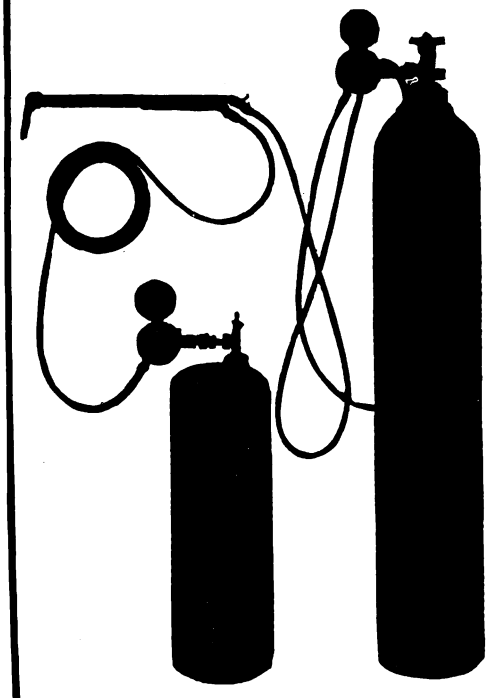
It preserves and protects the finish.

Applied with sprayer, which deposits the liquid in a fine mist evenly. Then polish with a cheesecloth. It is extensively used in Public Garages and by Automobile Owners. A trial makes a constant user.

If your dealer cannot supply you, send us his name.

The Wonder-Mist Co., 14 Federal St., Boston, Mass.

The ALLEN TIRE CASE



The tire case for spare shoes has come to stay, because it has a real reason for existence. The spare shoe must be protected from the deteriorating effects of sunlight, water and oil, and for this purpose the Allen Tire Case has demonstrated its positive value. The Allen Tire Case is made of highest quality enamel duck, in all sizes, and in all colors to suit. Prices $3.00 and up. Send for illustrated booklet.

$1.00 invested in the handy, accurate Allen Tyrometer, air pressure gauge, may likely save you many dollars in tire bills—it's the only way to **know** the air pressure in your tires.

At your dealer's, or write

Vanderpool Vulcanizers Satisfy

A. W. Childress, Richmond, Va., July 3rd, writes: "The machines that I bought from you have been in use every day, and the more I ***use them, the better I like them.*** I consider your Vulcanizer ***the equal of any on the market*** and ***better than most.***" Mr. Childress bought one Vulcanizer and after using it about 4 months, he sent us his order and check for a second machine.

Moler & Steward, Mount Orab, O., July 1st: The Vulcanizer is working fine. We have had no trouble with it since we got it. ***It is doing fine work.***

A. M. Johnston, Mechanicsburg, O., June 1st: The machine is doing good work. I am well pleased with it.

W. D. Patrick, Elba, Alabama, May 20th: Am turning out quite a nice lot of work with the Vulcanizer. Well pleased with it.

Wheeler & Wheeler, Columbus, O., June 24th: We have the machine set up and doing fine work with it.

A Vulcanizer that satisfies others is a good one to start in business with. They do good work in our shop and they will in yours.

Catalogue on request.

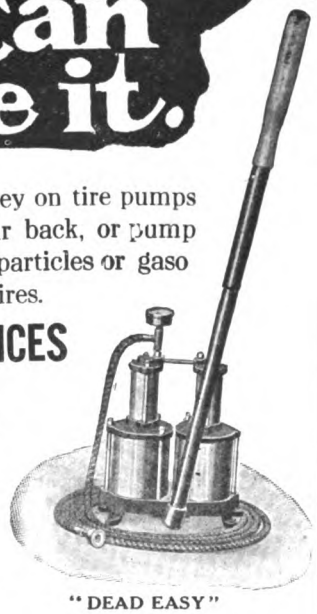
VANDERPOOL CO. - Springfield, Ohio

NATIONAL RUBBER TIREFILLER

An ingenious treatment of small Pure Rubber particles which holds them together in solid form—solid enough to carry the heaviest load your engine will pull—resilient enough to give that "ON AIR" feeling that brought popularity to pneumatics—cannot puncture, rim cut nor blow out—makes your tires cost less by wearing longer.

National Rubber Tirefiller in your tires is like Tire Life Insurance Policies—they insure you more miles out of your tires—complete freedom from all tire trouble—against serious accidents from blown out tires and the real tire service you are entitled to.

It eliminates the delicate and expensive inner tube entirely—it replaces uncertainty with certainty and makes your car absolutely dependable. Let us send you small sample and tell you more about them.



NATIONAL RUBBER FILLER COMPANY,
208 College Street, MIDLOTHIAN, TEXAS.

At Our Risk—You Can Prove it.

Don't waste good money on tire pumps that either break your back, or pump **Rubber Rotting** oil particles or gaso line fumes into your tires.

TAKE NO CHANCES

At our risk you can prove that the **"Dead Easy"** is quicker, safer, easier and cheaper than any other tire pump, either engine drive or hand power.

"DEAD EASY"

Convenient to carry with any car, it is always ready for instant service. The gauge showing exact tire pressure, there is no guesswork—and it's "Dead Easy."

A FAST WINTER SELLER FOR FORD AGENTS.

THE NEW INVENTION, *"Fillometer."* Every Ford Owner is a Prospect.

The ***"Fillometer"*** is a Combined Gasoline Tank Filler and Gasoline Gauge. Anyone Can Install it in 2 Minutes with a Screwdriver.

No More Crawling Out and In When Filling with Gasoline. A Great Comfort Particularly In Stormy Weather.

If You Once Install a *"Fillometer"* You'll Never Part With It

THE GAUGE SHOWS CORRECTLY HOW MUCH GASOLINE IS IN THE TANK.

Agents, Write For Particulars.

APEX ELECTRIC MFG. CO.,

1410-12 W. 59th STREET, CHICAGO, U. S. A.

The HUNTER

At Last, Mr. FORD OWNER! A SELF-STARTER For $10

Increases the Value of a Ford Three Times

NOTE THE ADVANTAGES

Powerful—The straight pull and powerful leverage enables a woman or girl to start it.

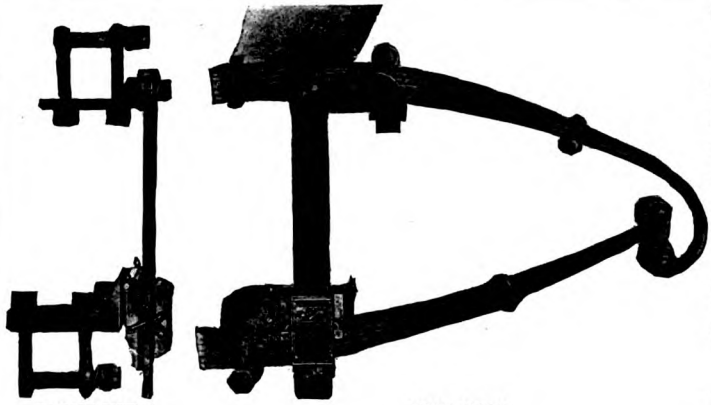
Simple—Installed in one hour. Nothing to get out of order.

Inexpensive—Costs little. No operating or installation expense.

Convenient—Easier to start motor from seat than from the crank.

Reliable—Entirely mechanical—can't fail to turn motor. Special attachment to close air intake of carburetor for easy starting in winter weather.

Appearance—Handle on dash all that shows. Crank not removed from front.



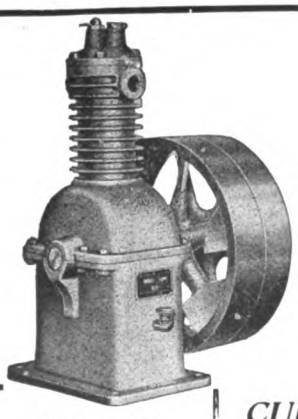
Every Ford Owner wants to make his car up-to-date and at the same time provide for comfort.

FORD OWNERS:—Write today for full description, or order through your dealer or direct from us.

DEALERS:—Don't fail to get our proposition at once. **Big money for you in this—the lowest priced reliable Ford Starter made.**

HUNTER LOCKS FOR FORD CARS:—A simple bracket and lock attached to steering column, making it impossible to steer car when locked. **Price, $1.00. Quickly installed. Sold by leading dealers.**

THE HUNTER AUTO SUPPLY CO., 4101-5 East Ravenswood Avenue, CHICAGO, ILL.



FRONT VIEW SIDE VIEW

THE car springs with the shock absorber attached are like a compound bow and arrow of great power. When the springs rebound there is a brake on the arrow or rod of the shock absorber, resulting in an easy upward movement. The shock absorber will outlast the car.

Simpler, more reliable than any other, requires no care. Money back guarantee. They are cheaper than car repairs, wear and tear, besides the ease of riding.

Wanted—Business-Getting Agents.

FRICTION SHOCK ABSORBER CO., Kingston, N.Y.

MADE IN FOUR SIZES.

AIR FREE FROM OIL—

THAT IS WHAT YOU MUST FURNISH TO YOUR PATRONS IF YOU WISH TO GIVE THEM GOOD SERVICE.

CURTIS GARAGE AIR COMPRESSORS

will furnish AIR FREE FROM OIL because unlike all other air compressors the amount of oil furnished the cylinder is controlled—only sufficient oil furnished to properly lubricate without excess to be carried over into the air line. Examine the cross-section illustrated and note that neither crank nor connecting rod dip into the oil and the oil is not thrown direct into the cylinder.

Write Us For Full Particulars Of Either Stationary or Portable Outfit.

WHY REPAIRMEN SHOULD USE Marko STORAGE BATTERIES

It is an easy matter to convince Automobile owners that it is economy to use the best battery that money can buy.

Probably their previous experience with unreliable batteries will enable you to prove to their satisfaction that the "Marko" is the one they should use.

Now is the time when you should go after business.

Spring overhauling is at hand and batteries for starting and lighting purposes are an important item.

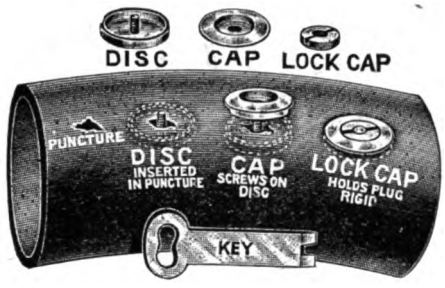
"Marko" batteries lead because of their great efficiency and reliability.

Write At Once for Our Proposition to Repairmen and Dealers.

PAUL M. MARKO & CO., 1191 Bedford Ave., BROOKLYN, N.Y.

SPITLER PUNCTURE PLUGS

The Spitler Puncture Plug repairs punctures in automobile inner tubes quickly and without the use of cement, assuring a safe, permanent and economical repair.



The operation is so simple that a lady can make the repair without soiling her hands.

The plug can easily be taken out and used over again. A permanent repair in one minute.

To insert The Spitler Puncture Plug into the puncture, wet the tube before inserting plug.

Place the base of plug on edge and by stretching the tube at point of puncture, the plug slides in like a button in your coat. Then place cap over discs and screw lock cap firmly.

The Spitler Puncture Plug positively cannot cut the tube nor injure the fabric of the shoe for the principle is the same as the air valve on the tube.

Write for Circular.

Price—Four to a Set, $1.00.

(Patented May 11th, 1915.)

SPITLER PUNCTURE PLUG CO., Inc., United States Rubber Building, 1790 Broadway, NEW YORK CITY

Keeps Your Car Looking New

Midget Outfit, With Cloth, $1.00 Giant Outfit, With Cloth, $1.25
Refillers—Pint, $0.75 Quart, $1.00 ½ Gallon, $1.75 Gallon, $2.75

1 Pint of Marvel-Mist is equal to 1 gallon of ordinary polish.

Write for our attractive Dealer's Proposition.

MARVEL-MIST MANUFACTURING CO., 56 Greenpoint Ave., Brooklyn, N. Y.

PREMIER AUTOMATIC ELECTRIC VULCANIZER

CAN'T BURN TUBES WITH THIS.

"Press the button and forget it." No watching—no danger from an open flame. Automatically cuts off heat when casing or tube is vulcanized—cannot burn repairs. Good profits for dealers in selling the portable Premier. Complete outfit $3.50. Operates from battery or 110 volt current for garage use. ***Write us.***

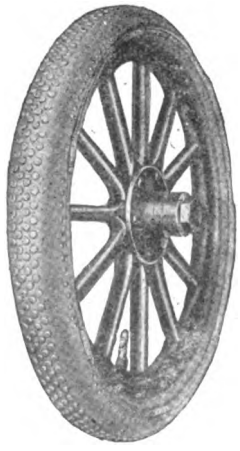
Three Comforts for Fall and Winter Motoring

WOODWORTH TROUBLE-PROOF TIRE
EASYON TIRE CHAINS
WOODWORTH LIGHT WEIGHT NON-SKID TIRE COVER

Woodworth Trouble-Proof Tires are guaranteed against punctures or blow-outs for 5000 miles. By using Woodworth Trouble-Proof Tires you avoid the danger of having to freeze your hands repairing or changing tires in cold weather.

The Woodworth Trouble-Proof Tire is protected against punctures by a strip of chrome tanned leather which does not stiffen the tire and does not make it ride hard or overheat. If you do not find these tires ride fully as easy as plain pneumatic, we will refund the full amount paid for them. Think of the satisfaction of knowing that your tires are proof against trouble.

EASYON TIRE CHAINS



Every automobile should carry a set of Easyon Tire Chains. They can be put on in a moment to prepare you for slippery going. Even if you get stuck in the mud or snow, you can put them on easily.

They have leather covered fasteners that do not injure the spokes and specially designed cross chains that do not cut the tire.

Price $3.20 per set for tires up to and including 4 inches.
Price $4.00 per set for tires larger than 4 inches.

Sent prepaid to any part of the U. S. or Canada.

WOODWORTH LIGHT WEIGHT TIRE COVERS

are much lighter in weight than other covers; have studs of special steel that grip firmly on asphalt or brick pavements; have a fastening that automatically tightens them and have the leather on the inside finished by a special process which makes it adhere to the rubber, preventing chafing or wearing of the tire. These are very low in cost and are just the thing for a man who wishes to be protected from tire troubles in the winter and wishes to have a non-skid that will be always in place.

Send for full information and prices

Automobile Dealer and Repairer

A JOURNAL OF PRACTICAL MOTORING

Registered in the U. S. Patent Office

VOL. XX, No. 2 NEW YORK, OCTOBER 1915 PRICE { 10c PER COPY / $1.00 PER YEAR

FOR REPAIR WORK.

Why It Pays to Use a Lathe and a Milling Attachment.

From J. N. Bagley, Nebraska.—If one were to carry in stock all the repair parts for the different cars that come to his place he would have a large investment and also a stock that might never be used. In case of a couple of dozen different makes of car in the neighborhood it would be quite an item to carry in stock even the axles, although many of them are liable to break. The writer found a better way is to have the necessary tools to make some of the parts, such as axles, transmission shafts, etc. These are in no way difficult to make and to supply them will require only cold rolled steel which is a small item.

As to the tools for making parts, it requires only a small outlay of cash and when they are installed they can be used many times for general repair work. A lathe will be necessary, with a milling attachment, a few milling cutters, and an arbor for holding the wheels between the centers of the lathe while in use. The outlay for a 13 inch lathe will possibly amount to $200. At once one will remark that it will not pay, but the writer makes in his shop

Fig. 1.

more than one hundred axles of various kinds during a season and the price ranges from three to eight dollars. Many of these are made for the garage in the neighboring village.

But we will consider an investment of $200 for the lathe equipment and the interest on it at 8 per cent. as $16 per year in case the money is hired. Let the shafting be figured 1¼ inches for an average; some will be smaller and very little of it larger, so we will average it at this size. This will make the raw stock cost 45 cents for an axle. Complete axles run in price from three to eight dollars and it will take from two to four hours to make one of them on a lathe. Reckoned 3 hours at 60 cents an hour, it makes a total cost of $2.25. The axle sells for $5, leaving a profit of $2.35 per axle. Figuring 25 of these axles, which is a very low figure considering the number of cars in use, and we have a net profit of $58.75. We also have 75 hours labor at 60 cents to the hour that would not have been added to the profit column had it not been for the lathe equipment which amounts to $45, making in all $103.75. Now we will pay the interest on the investment which is $16, and we still have to the good $87.75. If the lathe has been cared for and oiled it is not damaged or worn enough to mention. All the while it can be used for the general repair business and bring returns on the investment. A tool, so far as value is concerned, is worth what it can earn, and its earning capacity depends on the ability and push of the mechanic using and operating it.

Then the question arises, can any one run a lathe and make an axle for a car? It is a very simple operation, requiring only a mechanic with average ability.

In Fig. 1, we have a drawing of an axle of a very common type and not at all difficult to make. The axle A, has a square at one end B, which slips or fits into the square hole in the differential gear. The

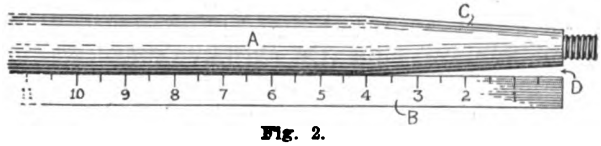

Fig. 2.

other end C, is tapered for a taper hub and is supplied with a key seat D, to key the wheel to the shaft to prevent it turning inside the hub. The end at E, is threaded for a nut which in turn prevents the wheel working from the shaft. Now it may look at first difficult to make such as the tapered end, and the square at the opposite end. Then there is the key seat and the thread on the end. A hard job, they will all say who have never made one. But stop for a moment and reason it out, and see what there is hard about it, after all.

We will first take the taper of the axle, as shown in Fig. 2. The axle A, is turned to size and we must turn the taper C. Lay the straight edge B, on the shaft as shown in the drawing and we find that the taper is 4 inches long and the space at D, is ¼ inch. Now we have it in a nutshell, so to speak, a ¼ inch taper in 4 inches. Now let's see how difficult it will be to find how far over to set the tail stock to turn the taper.

On shaft A, in Fig. 3, we have measured back from

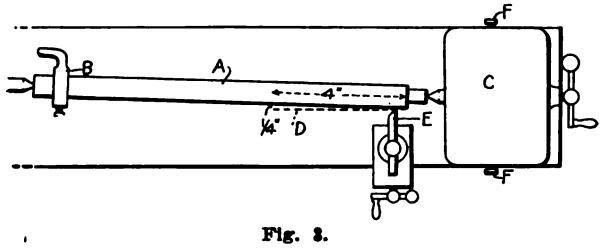

Fig. 3.

the end 4 inches, as shown at D. Now we will set the tail stock over until we can start the cutting tool E, at the outer end, and in running it 4 inches have a space of ¼ inch, at D. We are now set for turning the taper jaws in ordinary turning. The tail stock C, can be tightened, and locking or adjusting screws F, set tight on each side, and the lathe dog B, made secure and we are ready to turn the shaft. Continue to turn until the four inches is cut as marked and the taper is finished. A good plan when turning an axle for a certain car such as a

Digitized by Google

Model 31 Buick, is to have a little tab and mark down the amount of the set-over of the tail stock and in the future this will save some little time in setting it by measurement each time.

Now let us see how difficult it is to cut the thread on the lathe. In Fig. 4, at A, we have the axle with the thread on it, or in other words, the old axle, and we must know how small to turn the end B, to be threaded. In this case I will set the calipers C, as shown in the drawing, on the outside diameter of the thread and turn the end B, of the axle to a size that the caliper C, will just slip over with the same pressure that it does over the threaded end. The end at B, should be rounded a trifle at the nose to permit of the nut starting easy after the thread is cut. Also the end to be threaded at B, should have the depth of the thread cut out at the shoulder, A. Now it will be necessary to know the number of threads to the inch to set the gears on the lathe to do the work. For this information we will use a thread gauge as shown at E, which is a little tool with notched blades. When the correct blade is found it will fit into threads F, perfectly and the number of threads to the inch will be found stamped on the blade. Consequently we have measured the shaft D, and find that the threads are so many to

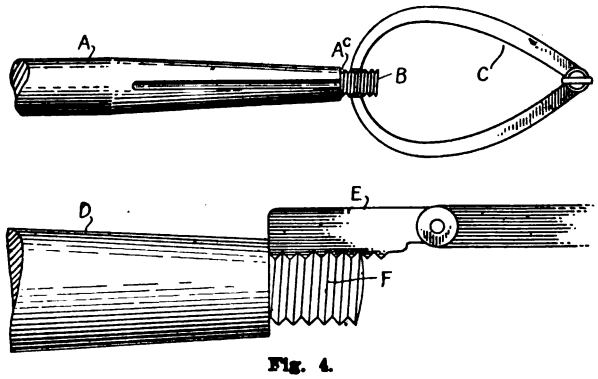

Fig. 4.

the inch. Now by referring to the thread gauge plate attached to the plate, the gears can be used in cutting the thread.

Grind the tool until the point will perfectly fit the notch in the thread gauge that we found the number of threads with, and smooth it up on the oil stone. Now we must place the tool in the post in such manner that the thread will be true and not have more of an agle on one side than the other. To do this we apply the little gauge D, to the shaft A, on its straight surface, as shown, and by setting the cutting tool E, into the notch on the side—still keeping the tool on the shaft—the position of the tool will be such that it will cut a perfect thread. The shaft will revolve on center B, at C, as in turning. Move the carriage back to the starting position and adjust the tool to make the cut. Start the lathe and allow it to cut to the shoulder and withdraw the tool from the work. Reverse the lathe and allow the tool to be carried back for the second cut. Repeat the operation until the thread is finished and the nut will screw on with very little crowding with the wrench.

The speed of the lathe should be quite slow in thread-cutting, especially on cutting a short thread, as one is liable to allow the tool to gouge the work before he can gain control of the machine. In case it is necessary to remove the tool for grinding during the operation, reset it again with the gauge as shown in Fig. 5, also being very careful to have it so set that it will enter the same cut exactly as before. In case the lathe is equipped with a compound rest the tool can be moved back and forth without loosening it from the post. The cut taken from the shaft should not be taken too heavy as it will tend to make the thread rough and ragged. The cuts should be made light and with just enough speed of the shaft to make the cut clean.

The milling attachment for the lathe consists of a vise arrangement which can be adjusted up and down, and which can be bolted to the carriage. These

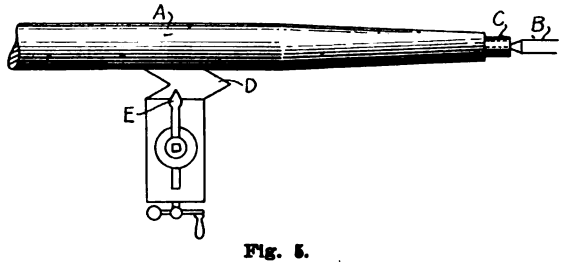

Fig. 5.

devices are not at all expensive and any lathe builder can furnish or recommend one suitable for the lathe they make. In Fig. 6, we have the arbor for carrying the wheels to do the milling. It consists of a shaft, one end of which is turned down and threaded as shown at B. As indicated by the dotted lines the shaft is smaller and over this is slipped the wheels, together with many rings, or washers as we call them, varying in thickness from one-sixteenth to one-half inch. These washers C, permit of the wheels being spaced to meet requirements. The milling cutters A, should fit the shaft B, perfectly tight, so that they will not tighten out of true. Each end of the shaft is supplied with a center G, to permit of it being hung between the lathe centers. The nut E, screws over the threaded end of the shaft F, holding the wheels from turning on the shaft when in use.

The wheels in this instance can be adjusted to cut the shaft D, on two sides at once, thus saving time by cutting one side at a time. These milling cutters are not expensive and one should have a variety of them on hand for special jobs, as well as the stand-

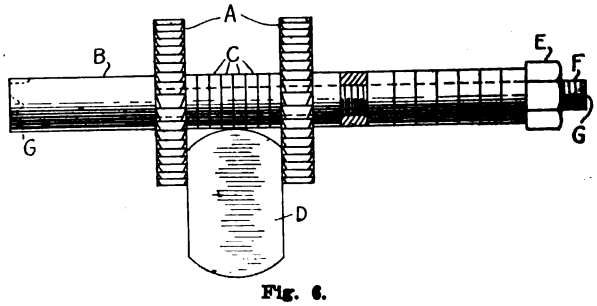

Fig. 6.

ard thickness for cutting key seats. The cutters should not run at an excessive speed or the cutting edges will be torn and broken. I have found that a key can be cut the full depth at one cut better than it can be cut shallow, and repeated.

Another method of squaring a shaft or cutting the key-way is shown in Fig. 7 in which the shell end mill is employed. This method, however, for squaring is not as efficient as the one just described but it can be done in case the other cutters are not at hand. The mill can be chucked, if a straight shank, or in case a taper shank, it can be used in the

Digitized by Google

taper of the spindle. A represents the head stock of the lathe, and B the chuck we are holding, which is operating on the shaft D, cutting away on the side of E. In this instance as the cutter is smaller it will be necessary to feed the work against the cutter up and down as well as crosswise.

We have gone over the operations which are necessary in making an axle of an automobile and find it is not a serious undertaking, after all. When we consider the advantage such a shop has over one not equipped for this work, it bears quite heavily on the mind of the person getting the repair made. The shop that can turn the car out with the least delay

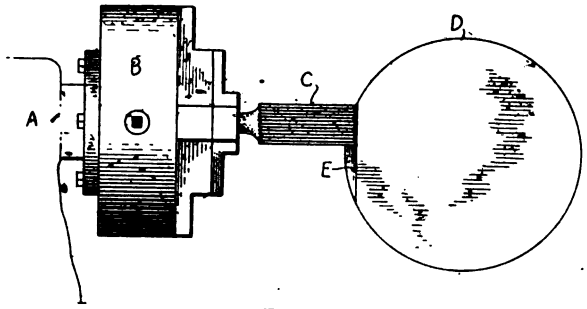

Fig. 7.

will invariably get the work. I have known of cases where cars have been held up for two weeks because of a broken axle.

As a matter of dollars and cents it seems that it would be a wise thing for every man operating a garage to get in touch with a lathe manufacturer and install a lathe outfit, and let the motoring people know he has it and can use it.

DRY BATTERIES.

Their Evolution and How They Can Be Made to Give Good Service.

BY SYDNEY F. WALKER, M. E.

No. 4.

The cost of renewing the whole of the cell was small in labor, and therefore the advantage, once the dry cell came within reasonable limits of endurance, was on its side. At the present time though wet cells of the various forms mentioned were made from gas retort carbon, and it was quite a common experience for a lamp to burn satisfactorily for some time and then to give a splutter and a blaze and be temporarily extinguished. The splutter and the blaze were caused by the presence of some impurity which had a lower melting point than carbon; and which was converted into vapor at a very much quicker rate than the carbon was, with the result given. The carbons employed for wet Le Clanché cells, while they are made with a considerable amount of care are still hardly suitable for dry cells. In the process of baking the carbons a hard scale is left on the outside. The scale tends to prolong the life of the carbon, but it introduced an unnecessary resistance into the path of the current, and into the path of the liquid which is so largely employed in carrying the current. In the writer's experience, in the best dry cells, pieces of arm lamp carbons and of the very best forms are actually employed. In the best arc lamp carbon again no glutinous substance is employed to enable the necessary cohesion to be obtained.

Dry cells are used generally for telephone work, for bell work, nearly always for mine signal work, and of course where primary batteries are employed for the ignition batteries of motor cars. But in order that the dry cell should take the place of the wet cell it was necessary that it should be able to perform the work hitherto done by the wet cell without requiring renewal at too frequent intervals. In order that this might be accomplished it was necessary to provide in the dry cell a certain amount of oxide of manganese and a certain amount of sal-ammoniac, also a certain amount of water. The sal-ammoniac must be in solution. Further, it was necessary to provide a containing cell of some form. In some of the early forms of dry cell a porcelain containing vessel was used, and those cells which adopted that method stood up to their work at that time much better than those which did not.

In all dry cells, however, the zinc has been made the containing cell, sometimes reinforced by a porcelain containing vessel, sometimes by a padding of various substances with cardboard on the outside. The zinc is made sometimes into the form of a cylinder, sometimes of square of rectangular section. In the early days of the dry cell it was not usual to close the bottom of the zinc. The zinc cylinder formed the containing vessel only so far as the sides were concerned. In the modern dry cell this has been changed. The bottom of the zinc containing vessel, whether it be cylindrical or square, is closed with a substantial foot also of zinc, the foot and the upper portion being carefully burnt together. In closing the longitudinal seam of the cylinder or rectangular vessel also care has been taken to burn the zinc together, not to solder it.

Fig. 14 shows two zinc containing cylinders, one cylindrical in form, and the other square in section. It will be noticed that a wire is connected to the top

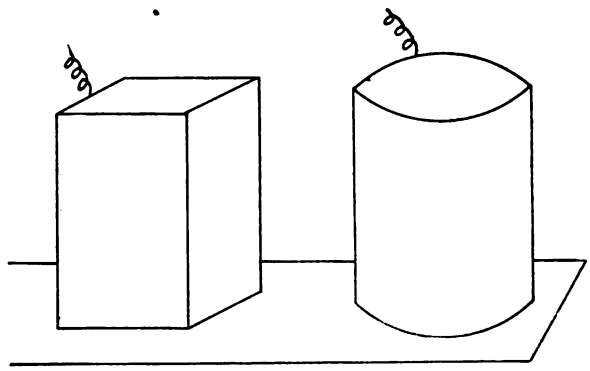

Fig. 14—Forms of dry cells square and cylindrical with wires attached to the zinc cylinders ready for connecting to the next cell.

of the zinc containing vessel in both cases, the wire is merely soldered on, and it is for connection to the next cell. Incidentally it may be mentioned that this connecting wire is often a great source of trouble. It is very apt to break off at the top of the zinc. That difficulty has been overcome in the better form of dry cells by making the connecting wire of fairly large gauge, No. 16 or even No. 14 copper wire, by having the wire of soft flexible copper and by very carefully "sweating" a fairly long length of one end of the wire to the zinc.

A point that should be mentioned here is that solder must not be used for completing the zinc containing vessel. The solder that is used for attaching the copper wire to the zinc must be kept well above the point at which chemical action can go on.

Digitized by Google

There is no difficulty in doing this and in the best batteries it has been done. Another point that should be mentioned here is that with dry cells the water employed should be absolutely pure distilled water.

For the dry cell a pure carbon plate or rod of some form is the first desideratum. Again the substance of which the carbon plate or rod is made must be absolutely pure carbon. The same reasoning applies here as in the case of the oxide of manganese, and the crushed carbon that goes with it; any impurities, any foreign substances will tend to set up either additional resistance or opposing pressures or both. The carbons which are now used in ordinary Le Clanché cells are prepared in exactly the same manner as those for electric arc lamps. It will be remembered that for arc lamps the very purest carbon is required.

A point that requires considerable attention is how to provide the largest amount of water or the largest quantity of salammoniac solution. In the dry cell, once the cylinder of carbon and manganese is in its place, inside of the zinc cylinder, and with the salammoniac also in place there was nothing to cause it to get out of place, and so a very much lower compression could be employed and also a solution of salammoniac could be employed to act as a partial coherer. From what has been said it will be understood that the cylinder of carbon and manganese would be porous and that the pores, if the cell is to work satisfactorily, must be filled with a solution of salammoniac. Hence by kneading the carbon and manganese with a solution of salammoniac the path for the current is provided.

The process then is, the very highest grade oxide of manganese is obtained; it is crushed to a very fine powder, all lumps being removed, and all possible impurities that show being abstracted; carbon of the very highest purity is also crushed to a very fine powder; the powders of oxide of manganese and carbon are thoroughly mixed together, and they are kneaded into cylinders, around the carbon rods or

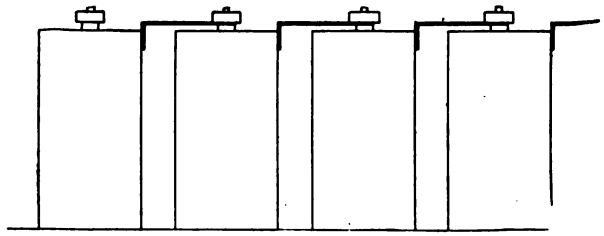

Fig. 15—Diagram showing how dry cells are connected in series.

plates, under hydraulic pressure, but with only sufficient pressure to keep the whole thing together, and to reduce the resistance to its lowest figure. It should be noted again, that providing the carbon and maganese are pure, squeezing them up together by hydraulic pressure, tends to lower their resistance. If it were not for the presence of the salammoniac employed in kneading them up into blocks, the close pressure would be against the continued work of the cell. Too close a pressure, even with the salammoniac used as a coherer would also tend to reduce the working life of the cell.

The block of carbon and manganese surrounding the carbon plate or rod having been made, the cell is completed by the addition of the very purest salammoniac that can be obtained, ground into a very fine powder, and mixed into a paste with distilled water, the space between the block of carbon and manganese and the zinc cylinder being filled as full as it is possible by pressure from above, with the paste. The salammoniac paste is not carried up to the top of the cell. It is kept below the point at which the wire is attached to the zinc rod, and usually some little distance farther down. From ½ to 1 inch is usually left free of salammoniac at the top of the cell.

Now comes in the other measures that have been taken to increase the working life of the cell. It will easily be understood that as the supply of liquid in the cell is strictly limited, it is of the greatest importance that none of it shall be allowed to evaporate. It is all required for use in the chemical actions of the cell itself. The practice is to fill in above the salammoniac with some substance that absorbs

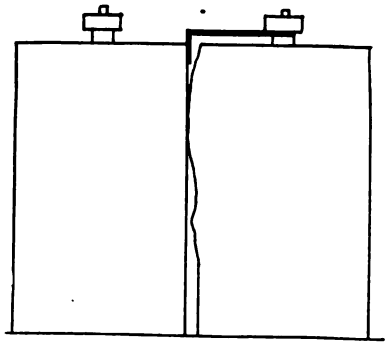

Fig. 16—Diagram showing the zinc containing cylinders of two dry cells touching.

water, and then to pitch over the whole of the top, from the carbon block to the zinc cylinder, and in some cases to fit the glass vent tube. The cell is completed by protecting the zinc plate on the outside with some cardboard wrapping. The object of the cardboard wrapping, which is also made use of as an advertisement of the cell, is to prevent the connection between the zinc cylinders of adjacent cells. When cells are working together, they have to be connected zinc to carbon, zinc to carbon in succession, as shown in Fig. 15. If two zinc cylinders touch, as shown in Fig. 16, one of the cells is cut out of action, and the current furnished by the battery as a whole is less by the pressure of that cell, divided by the resistance of that cell, practically by the pressure of the cell.

What Dry Cells Will Do.

It will be understood from what has been said that what a given battery of dry cells will do, depends directly upon the amount of oxide of manganese and salammoniac that the individual cells contain. It is probable that the work done in furnishing current for ignition of a six or eight cylinder engine, through an induction coil, is at least as great as that involved in furnishing current for lights. The difficulty is, that it is not easy to estimate the current required for the ignition work, while that required for lighting is well known, and is easily calculated. For lighting purposes, there are now two kinds of lamps on the market, viz., the one watt lamp, and the half watt lamp; and the latter, as the writer understands, has been used with considerable success for motor car work. It is a peculiarity, as he understands the matter, of the manufacture of the half watt lamp, that it lends itself to very high powers, from 500 C.P. upwards, and to very low C.P.'s, such as those required for the lights of motor cars. The reason is, the pressures in both cases are low. With very high efficiency incandescent lamps,

Digitized by Google

those in which the temperature of the filament is at a very high figure, the lower the pressure at which they are run, the easier is the problem involved in making them. The higher efficiency lamp, the half watt lamps, in which very fine filaments are curled into small helices, as shown in Fig. 17, the lamp bulb is filled with the inert gas nitrogen. The higher the pressure at which the lamp is worked, the smaller is the size of the wire forming the filament; and the higher the C.P. again, the longer is the filament. It will probably be seen how these two qualities lend themselves to the making of lamps for motor car work. In the writer's view also, they lend themselves to working with dry batteries, because the current required is so much smaller.

Lamps employed for motor cars range from 2 C.P. up to 16 C.P. For headlights a lamp of 8 C.P. focussed in a lens of the proper curve, will give a powerful beam of light over the arc where it is required. It will be remembered that by the aid of a reflector, and a lens, the back rays from the lamp and the side rays are utilized, the back rays being reflected out to the front, and the side rays being refracted in the same direction. For 8 C.P. lamps, with the wire filament, an efficiency of 1 watt per candle is required; that is to say, 8 watts, or with a battery furnishing 8 volts, 1 ampere. With the half watt lamp only half that amount of current is required, with the same pressure; that is to say, the 8 C.P. lamp requires only 0.5 ampere with a battery furnishing 8 volts. Taking again the requirements of an automobile as two 8 C.P. lamps for headlights, one 2 C.P. for the tail light, and a 2 C.P. for the dashboard, we have a total of 20 candles required.

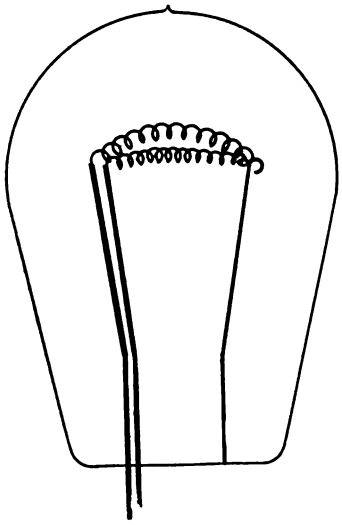

Fig. 17—Diagrammatic representation of the filament of a half watt lamp The filament consists of a very thin wire coiled in a spiral.

The practice with accumulators is to work either 6 volt or 12 volt lamps. This would mean that the combined 20 C.P. of the four lamps would require 10 watts, and at 12 volts 5/6 of an ampere. The 12 volts can be obtained by a battery of six accumulators. The 6 cell accumulator only gives its 12 volts just after charging, and it is allowed to work down until each cell gives 1.8 volts; that is to say, till the 6 cells give 10.8 volts.

(To be continued.)

Electric cables that rub on sharp edges of battery box or other parts, will soon wear through the insulation from vibration of the car, and a short circuit will occur that may be hard to locate.

NOW SEE AMERICA.

It Is Worth the Cost and Europe Is a Good Place to Stay Away From.

From J. J. Cole, President of the Cole Motor Car Company.—Christopher Columbus in 1492 simply located the continent of America. The summer of 1915 has marked its real discovery. And in the great enterprise that has brought America into her own, the present conflict in Europe and the motor car have been the two big contributing factors.

Ever since the first clash of arms on the continent across the Atlantic, the American tourists have been forced to look elsewhere for their summer rambles, and with the warfare carried to the seas, came the knowledge that they would have to content themselves within their own land.

Robbed of their Paris, their Berlin, their London, their Karlsbaad, their Ostend, their Heligoland, their Rome, their Florence, their Alps, their Tyrol, their Monte Carlo, the American people have turned their gaze from the lands across the seas and have concentrated it on their own shores. From a nation of curiosity seekers abroad, they have become a nation of domestic explorers, and the land which had remained hidden from them, because of its very proximity, to their surprise has opened before them like a treasure cave, revealing new beauties, new splendors, new opportunities, new paths of adventure, of which they little knew, or seemingly cared to know.

The reports of the great 42-centimeter guns on the battlefields abroad have been as a thundering "Open Sesame" to these modern American Ali Babas in search of excitement. From the art and culture of Europe they have turned to the natural beauties of their own country—and in them have found a rich reward.

From Maine to California, from the pine clad forests of the Northern Peninsula to the tropics of torrid Texas, they have found the fulfillment of the prophesy that sent the medieval adventurers forth from the ports of the Old World. America, the Promised Land, the dream of Europe four centuries ago, in its twentieth century reality, has been revealed to them as a land of even greater promise.

During the last three or four months there has been more touring over the highways of the United States than ever before in its history. The great rush to the West in '49 fades into insignificance beside the westward flow of the summer of 1915.

The slogan of a few years ago—"See Amercia First"—has been changed to "See America Now" and the American people are promulgating the doctrine as a national policy.

Aided by the good roads campaigns, waged so assiduously in all parts of the country, the American tourist has found the open road a veritable boulevard. Distances which before loomed up forbiddingly, now skim unnoticed beneath the wheels of the motor car. Miles seem meters and the great American out-of-doors has become every man's front yard.

I have just returned from a trip by rail to the West, and as I glanced from the window of the passenger coach, wherever a highway paralleled the track, I saw happy, dust laden American automobilists—not by the dozens, not by the scores, but by the hundreds. The roads were alive with them, day and night, and there was not a one that did not fairly buzz with the drone of busy motors.

The American people have taken to the road.

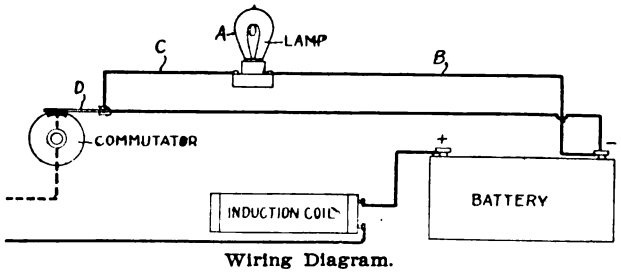
Digitized by Google

They are searching the very heart of the continent. And America, who, like a great bird, has been hovering with wings outstretched, beckoning for four centuries to a brood that always turned a deaf ear to her call, has received them at last, bestowing upon them rewards more glorious than Europe, the fascinating, ever could boast.

The great European war, though it is disintegrating the Eastern Hemisphere, is amalgamating America—it is Americanizing it. As we have often heard, it is an ill wind that blows nobody good. The wind that is bringing to our ears the sound of suffering from abroad, is carrying out to the world from America the call of a new nationalism—the patriotic anthem of a newly discovered America, played by the auto horn.

Though the European war precipitated the situation, there were some who sensed it some years ago. We felt that inevitably the American people must come to a greater recognition of their own land and its possibilities.

At that time the Cole Motor Car Company was about to produce a new model. We sent it out into the West—into the very heart of the Rockies to test it.



Our engineers accompanied it, and when they returned they knew first hand what demands would be made of a car that was to travel this continent through and through dependably.

As a result, when we produced our Cole Eight, which was built to master every sort of road condition, we were forearmed. Coming as it did at the beginning of the year that would see more touring in this country than ever before, it was adapted perfectly to the demands of the time, and its success everywhere we have attributed to the foresight of those men who urged us some years ago to go out and test our model in the heart of the continent, where America exacts her greatest toll from a motor car—where only absolute efficiency can endure.

And now that the American people have come to know their land and appreciate it, and the builder of motor cars knows how to build his mechanism to withstand every test that touring in this country can impose, we look forward to a continuation of the era of prosperity which the motor car industry is enjoying. Though stimulated by the war in Europe, it will be fostered and furthered by the Americans who now understand.

Wire Testing from Commutator to Battery.

The illustration shown is a simple method to find out if the wires are in perfect condition from the

Wiring Diagram.

commutator to the battery, by placing an ordinary lamp, A, in a porcelain socket, and running a wire B, to the post of the battery, the wire C, to the commutator brush D. If the circuit, and the wires, are in perfect condition the lamp will light. The lamp method has proven a satisfactory way for testing.

COMPRESSION.

A Few Points That May Be of Interest to Inquiring Car Owners.

Frequently readers ask how much compression their engine cylinders have, or how much they should have. In every instance of this kind, we are obliged to give what may seem to them an unsatisfactory answer. To estimate cylinder compression with anything more than an approximate figure is impossible, without the use of a compression meter, and if a car owner wants to know how much compression the manufacturer aims to give, he should write to him for the information.

Normal compression in any given design of motor would be the compression (cold) fixed by the designer by the relation of the sweep of the piston to the clearance space. Normal compression is not the same, as measured in pounds per square inch, in all motors. The normal compression as against loss of compression would be evident to a motorist in the act of cranking. Were the compression to become abnormal, as a result of carbon deposit, it would be rendered manifest by knocking on a hill, or by way of pre-ignition.

The cold compression can be found by means of a gauge reading to about 90 pounds per square inch. Screw the gauge into the threaded hole, normally used for the spark plug. Another way is to use a spring balance, hooked to the starting crank, and by a steady up pull, against the compression, the pull in pounds resultant of the compression may be noted.

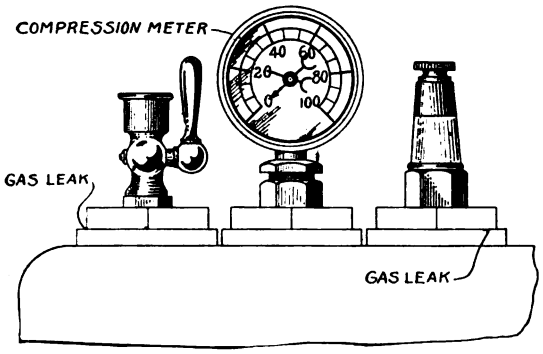
Assuming that the design is good and that a motor is in good working order, the allowable compression depends upon several factors as follows:

If liquid gasoline is entrained, upon the latent heat of evaporation of the liquid, of which gasoline is composed considering its complex character. The specific heat of the mixture, which will differ as the composition changes, it being the case that all the contents entering into mixtures are not of the same specific heat. The extent of scavenging, and the heat of the spent products of combustion, in the absence of complete scavenging. The temperature of the water in the water-jacket, or the efficiency of the air-cooling process, if air is used direct for purposes of cooling. The design of the cylinders, and the extent to which the surfaces maintain an even temperature; if some one zone on the surfaces is at a high heat, pre-ignition will follow, it being the case that this heated zone will be at the bottom of the trouble, nor does it matter if the zone is of small area. This trouble is most likely in cylinders of relatively large bore, in which the piston is likely to heat up at the axis of the head, which is the greatest distance away from the cooling medium, and it generally is the part in which the heat conductivity is a minimum because the metal is coated with a crust, due to elevated temperature, and the metal in the head is thin in order to have the piston as light as possible.

If the valves are not properly water-jacketed they are likely to heat above the desired temperature, and pre-ignition will be due to such overheat.

In some cases to make the motor as short as possible the water-jacket is so designed that but little of the cooling liquid will circulate over the dome of the combustion chamber, which is just the part that

Digitized by Google



requires the greatest amount of cooling, and pre-ignition will be eminent in all such cases.

Fins, seams, protuberances, etc., due to defective designing or misplaced cores in the foundry process, will heat up and they will be the direct cause of pre-ignition.

If the water circulation is not good, or if the amount of water circulated is inadequate, pre-ignition will follow. In some cases the water is enabled to short-circuit across from the inlet to the outlet without passing over the hot surfaces, and this is a prolific cause of pre-ignition.

Increasing compression tends to increase the terminal pressure, thus allowing and engendering an increase in speed of the motor without pre-ignition because the conditions of scavenging improve as a result.

Running on a "retarded" spark results in over-

How a Compression Meter is Used.

heating, and pre-ignition is likely to follow if the other (remaining) conditions are favorable.

Running on a mixture that is too rich will cause excess heating, which is indicated by a steaming cooler, and pre-ignition is likely to be one of the manifestations.

Although the compression of the charge during the second stroke requires the abstraction of considerable power from the flywheel, the work done upon the charge in compressing it is more than returned, during the power stroke. It is therefore found that with a high degree of compression, a high fuel economy is obtained, and a large output is secured from a motor of relatively small size.

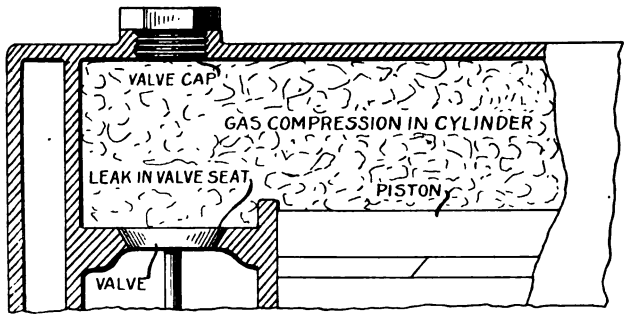
Much of the increased power for equal cylinder capacity is due to compression of the charge, because the most powerful explosion of gases takes place when the particles are in closest contact.

Another advantage of a high compression motor is that on account of the smaller clearance, less cooling water is required than with a low compression, as the temperature, and consequently the pressure, falls more rapidly. The loss of heat through the water-jacket is thus less in a high compression than in a low compression motor.

The difficulty about obtaining high compression is that if the pressure is too high, the charge is likely to ignite prematurely, as compression always results in increased temperature.

With gasoline vapor and air, the compression cannot be raised much above 85 pounds per square inch, but with the heavier fuels, such as kerosene, a compression as high as 200 pounds per square inch has been used economically. It has been the advantages of high compression that has turned the designer of automobiles toward the heavier fuels; but, with the increase of compression, there are many troubles in regard to loss of power and increased fuel consumption, owing to the wear of the valves, pistons and cylinders, which produces a loss in compression and explosive pressure, and a waste of fuel by leakage.

The compression in atmospheres of a motor may be found by dividing the cubic contents of the piston displacement by the cubic contents of the combustion chamber in cubic inches, and then adding one to the result.



To ascertain the compression in atmospheres of a motor, when the cubic contents of the combustion chamber are known: Let S be the stroke of the piston in inches and A the area of the cylinder in square inches. If C be the contents of the combustion chamber in cubic inches and N the required compression in atmospheres, then

$$N = \frac{S \times A}{C} + 1$$

Example: Find the compression in atmospheres of a motor of 4-inch bore and 6-inch stroke, whose combustion chamber has a capacity of 18 cubic inches.

Answer: Six multiplied by 12.56 equals 75.36, which divided by 18 gives 4.19 and 4.19 plus 1 equals 5.19, or the compression in atmospheres required. One atmosphere equals 14.75.

If it is desired to ascertain the compression in atmospheres of a motor, the combustion chamber of which is of such shape that its dimensions cannot be accurately calculated, its cubic contents may be found by filling the combustion chamber with water, and after removing the water, ascertaining its weight in ounces, and then multiplying the result by 1.72. This gives the capacity of the combustion chamber in cubic inches. The compression of the

Where Compression Leaks May Exist.

motor can then be readily calculated from the formula given herewith.

To discover if there are any leaks in the compression of a gasoline motor, a small pressure gauge reading up to 75 pounds should be fitted into the spark plug opening in the combustion chamber by means of a reducing bushing. When turning the starting crank of a motor slowly the gauge should indicate at least 60 pounds per square inch if the compression is in good condition.

To test for leaks, fill a small oil can with soapy water and squirt round every joint where there may be a possible chance for leakage. Get an assistant to turn the crank and watch for bubbles at the joints.

If the joints are all tight, next examine the condition of the admission and exhaust-valves and if

Digitized by Google

either of them needs regrinding, it should be done, first with fine emery powder and oil, then finished with tripoli and water.

When the valves have been ground to a perfect fit, if the compression still leaks, the piston rings should be examined, as the trouble will be found to be with them.

CONDUCTED BY M. KEITH DUNHAM, OXY-ACETYLENE ENGINEER, 50 CHURCH STREET, NEW YORK.

Readers are requested to state their questions clearly and fully, but as concisely as possible. It is hoped the information given will be of general interest as well as of value to each inquirer.

To Readers of This Column.

Questions need not necessarily be confined to how to use the oxy-acetylene apparatus. Owners or drivers are invited to make use of this department regarding practicability of welding or carbon burning. A proper understanding of these principles will often save considerable money and annoying delays. Subscribers who have equipments which they are unable to operate are invited to tell their troubles. Perhaps the thing which bothers you most may be very easily remedied by a simple suggestion.

Construction Dangers.

From E. H. Hanscom, Maine.—I would like to inquire a little about oxy-acetylene welding. I have a compound blow pipe that was used in an oxy-hydrogen stereopticon some years ago. I was not interested in welding then but it gave a very brilliant lime light with gases which I generated with my own outfit. What I wish to know is, can I not do welding by substituting acetylene for hydrogen and combining this right from the generator (without pressure) with the oxygen under pressure and how heavy welding could probably be done in this way with the oxygen under 200 or more pounds pressure from gas bag (as produced this lime light) and this acetylene from a small generator such as would feed a lamp? I think I read in some of your back numbers that acetylene was safer without pressure. The blow pipe I have has an aperture of about 1/16 inch. Would this be large enough to do light welding and brazing? By answering the above through your paper or otherwise, you will oblige a subscriber for five years.

Answer.—Yes, you can undoubtedly weld with such an apparatus as you describe. Just how long you will, however, depends on just how lucky you are—eventually your friends will decide just how natural you look. Your chances of continuing business, if you use such an equipment, are just about as good as if you stood in front of one of the 42 centimeter guns of the German army while it is in action.

I sincerely hope that everyone using a home-made apparatus or whose ingenuity leads him to attempt its construction will read this reply and digest it—remembering that I have no apparatus to sell and that my advice is disinterested in this regard. Unless you have a very complete understanding of the qualities of acetylene and oxygen, don't attempt to make an apparatus or you will be flirting with the undertaker.

Undoubtedly there are a large number of readers who have contemplated similar outfits. Quite a large number have undoubtedly constructed equipments along this general line, so that a detailed reply to Mr. Hanscom's question may result in considerably prolonging some lives.

The acetylene generator contemplated is one which is ordinarily used for lighting. Such a generator would probably deliver as much as five cubic feet per hour, yet the consumption of the welding torch would at times be several times this; therefore, it would be necessary for the generator to deliver largely in excess of the capacity. There is considerable heat created in the generation of acetylene. In a properly constructed welding generator, this is taken care of but in your case the temperature would keep rising to a point where acetylene becomes explosive and then, bang! and the next morning we would read of the dangers of acetylene.

The fact that such a gas is impure and very difficult to use to effect a weld is a secondary consideration.

Every generator for welding purposes, to effect safety, must be equipped with a water seal to prevent the return of the oxygen (or flame) into the generator. Check valves, muffler devices, springs, etc., are useless and the proper construction of a water seal is a matter of considerable knowledge. To use a generator without such a seal invites an explosion.

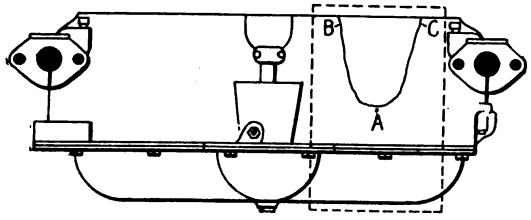
The oxgen generator you describe evidently is one using chlorate of potash and manganese dioxide which, when heated, give off oxygen. The present price of these chemicals is so high that your oxygen would cost four to five times as much as that which you can buy in cylinders and the latter, in addition, is considerably purer. This fact alone should discourage the generating of oxygen but here also is a danger element—the storing of oxygen under a pressure which is self generated.

The torch used for the oxy-hydrogen lime light certainly would be unsuitable to use with acetylene for several reasons. First, the weights of the two gases are very much different—therefore, your mixing chamber would be wrong. Second, you should understand that acetylene mixed with oxygen will burn backwards—against the flow—unless the mixed gases are traveling at a certain speed. Third, the construction of a welding torch to use acetylene under little pressure is one of very exact technical knowledge, demanding just the right size openings for each gas and having exactly the correct speed for the oxygen. (The latter feature would be impossible in your case, as you have no oxygen regulator.)

You are correct in your statement that acetylene is safer without pressure. To be exact, acetylene over 15 pounds begins to be dangerous—if it is in a free state. Dissolved, however, as it is in Commercial, Prestolite or Searchlight cylinders, it may be considered safe.

It would take a book of considerable size to properly show you the dangers you invite in the construction of such an apparatus. In this limited space practically all I can do is to point out the chief dangers.

Aside from the fact that life is precious and that a primary consideration always should be safety,



Digitized by Google

a properly constructed oxy-acetylene apparatus is always cheaper to use. With it you secure the right results, build your business and make customers and friends. Without it, and with impure gases, the weld is brittle or weak, you lose your customer and your business suffers.

Aluminum Welding Difficulties.

From Frank Erxleben, Indiana.—1. How can I avoid hairline cracks in aluminum? 2.—Give the proper way to weld a crankshaft. 3.—Also the proper way to weld a break in an aluminum crank case (Chalmers) broken as sketched below. Where should the weld be started, at A or B? Should the crank case be preheated? What action on the weld when welded inside and outside? A job of this kind always will crack on one side or the other when pretty tight patch is fitted.

Reply.—1—Hairline cracks are caused by the metal at that point not being strong enough to withstand the strain set up by welding or by improper heating. In aluminum cases, these cracks are most common where the alloy contains a large percentage of zinc, which metal tends to make the casting brittle. An aluminum casting with a high percentage of this metal must be very carefully supported when being preheated to avoid any stresses, as a jar or shock when the casting is hot, will form these cracks. Particularly notice that the casting is

Broken Crank Case.

heated evenly—remembering that it takes more heat for one inch metal than it does for one-eighth. If the break is close to a heavy lug, boss or bearing, bear in mind that this heavier section will absorb heat, or conduct it too quickly from the thinner adjoining section, which would result in the thinner metal cracking, unless you have kept the heavier section hot with other heat than the welding torch—that is charcoal or a gas torch, charcoal preferred. Of course you understand that your welding rod should be approximately the same alloy as the case and that the casting should be shielded from draughts while being preheated, during welding and when cooling. 2.—See answer in this column in the August issue to the Garden City Garage, Florida. If this does not cover your case, be more explicit and state make and model of car and in your sketch show clearly where the break is. 3.—Read carefully article on Page 51 of the August issue to get a better understanding of expansion and contraction. Of course a break of this kind requires preheating and it is very natural that the case will break "either on one side or the other" if you don't do this, for contraction must take place and cold metal must occupy a smaller space than when hot. Weld the patch (tack it) at points A, B and C. If you understand aluminum well enough, it is not necessary that you back up or support the heated area; but if you have trouble in the metal collapsing or your flame breaks through the weld often, make a mould consisting of 2/3 asbestos fibre and 1/3 plaster paris, well dampened, and put this back of the weld, and for a considerable distance each side of it. Allow this to dry thoroughly. Now see that the case is in alignment—you can determine this by fitting the cover plate in this instance.

In a charcoal fire, with the case covered with asbestos paper to protect it from draughts, heat slowly and carefully that section shown by the dotted lines, being careful that any heavy section in this general area gets more heat than the thin sections. When the case gives off a dull sound when tapped lightly with a hammer, you are ready to start welding. Keep the case in the fire when welding and keep all portions of it covered with the asbestos paper, except that section which you are welding.

If there are no heavy sections adjoining the weld and the case is properly preheated, it makes no difference at which point you start welding. I believe you will find in this case, however, a heavy section near A, which is used as a bearing and also along the general line A to C. Weld this first, remembering that a good welder will always bond that section adjoining a heavy one first, which will allow the "pull" caused by the heavy section to take place without causing a contraction crack. (Because there are still some sections unwelded and these sections will open up instead of the weld cracking.) Always study each cast, with this idea in mind, leaving until the last the weld which will join equal thicknesses.

Admittedly, the weld made from both sides is the best looking and if you can keep your case evenly heated all the time you are welding both sides, this is undoubtedly the best. But unless you have a very good helper, it is very difficult to avoid setting up strains by inside welding and alone you can easily weld from one side and make an absolutely strong weld.

You will find that you will not be troubled with the case cracking if you follow out these suggestions. Cracks don't just happen—there's always a reason.

Lugs on Cylinder.

From J. R. Cruikshank, Michigan.—In welding the lugs on a cylinder, broken off close to the holes, how can I preheat the cylinder without warping it?

Reply.—In a break of this kind, no preheating is necessary. Grind off the break, and have the metal at the weld and each side of it thoroughly clean. Be careful in "tacking" the broken piece that it is in alignment. Weld without preheating. After finishing, you will find that the cylinder is slightly out of round at this point, due to the pull, caused by the cooling weld. By using a portable grinder or a file, finishing with emery cloth, you will be able to fit the piston without machine grinding. While the cylinder is not absolutely round at this point, there is no particular harm done as it is considerably below the piston rings and the compression of the cylinder is unaffected.

Gear Welding.

From A. D. McLeod, Ohio.—Would you advise welding in a broken tooth in a pinion gear? How can I finish it and will the welded tooth stand up?

Reply.—Certainly. If only one or two teeth are broken, finish with a file. For a welding rod, use

Digitized by Google

one with a fairly high percentage of carbon—not the ordinary welding rod of Norway iron or mild steel. After welding and finishing, caseharden the entire gear in the usual way.

Welding Malleable Housings.

From Frank Erxleben, Indiana.—Please tell me in the October issue the best way to handle malleable housings, such as transmissions, rear differentials, an axle housings. 1.—When spelter wire is used it makes a job on the cracks, but when any strain such as body or springs or vibrations, even Tobin bronze does not seem to hold. 2.—What about some of the rods on the market called malleable rods? 3.—Will Norway iron with copper wire wrapped around it make a spring weld, or had it best be left alone entirely? 4.—Some welders say that a high heat puts malleable iron back to cast iron.

Reply.—1—Tobin bronze as a welding rod for malleable castings is by all means the best. Properly speaking this is a brazing job and not a welding one—therefore the casting should be hot enough for the bronze rod to flow readily, but not melting, as would be the case in a welding operation. I should not advise brass wire for several reasons too long to give here. Properly executed, malleable iron can be welded with Tobin bronze with the best of success. Your failure may be due to improper welding or a strain set up by welding, throwing the casting out of line and resulting in a break in use. Remember that while malleable iron is ductile and will not break easily, it certainly will warp unless you take the proper means to hold it in line.

Clean the break thoroughly, after grooving out the same as for any weld. Cleanliness in this case is even more important than in welding, as the bronze will not adhere to the iron if there are any foreign elements present. Preheat the casting if the break is such that there will be a strain set up by welding. Bring the break up to a bright red heat with the welding torch, without bringing the cone in direct contact with the iron, and be very careful that you do not melt any portion of the casting. Use plenty of flux and flow the welding rod into the break, without the cone of the welding flame touching it. Be sure the bronze really attaches itself smoothly—not in the form of a bubble. If the casting was poorly designed originally and was too weak for the purpose, you may reinforce it by laying wrought iron straps at right angles to the break and bonding these straps to the casting with Tobin bronze; but you will find this latter course I think wholly unnecessary if you properly execute your weld.

2.—Leave them alone.

3.—It will not. Some theorist originally advised this mixture for malleable iron. You can make a spring weld by using a welding rod of a slightly higher carbon content than the spring. The spring must be re-tempered, of course, after welding.

4.—If malleable iron is re-melted, it becomes a very hard, brittle iron—not the grey iron of castings you are familiar with. It is for this reason that you must be careful not to melt any portion of the malleable casting while you are brazing it.

Grinding aluminum is easily accomplished by using ordinary machine oil as a lubricant. It has no effect on the grinding wheel, which will last longer when grinding aluminum in this way than when grinding cast iron.

BATTERY TROUBLES.

Why Some of Them Occur and How to Guard Against Them.

Battery trouble as a rule is to be traced to want of attention on the part of the motorist, for, although it is undoubtedly true that defects do develop, a little attention and immediate action will usually serve to eliminate them. A golden rule is to observe the maker's instructions at all times and to avoid overloading the battery with accessories—electric horns and the like, for we may rest assured that no pains have been spared by the battery expert to ascertain the best running conditions for their productions.

Buckling of plates, sulphating, short circuits, broken and corroded terminals, leaky containing

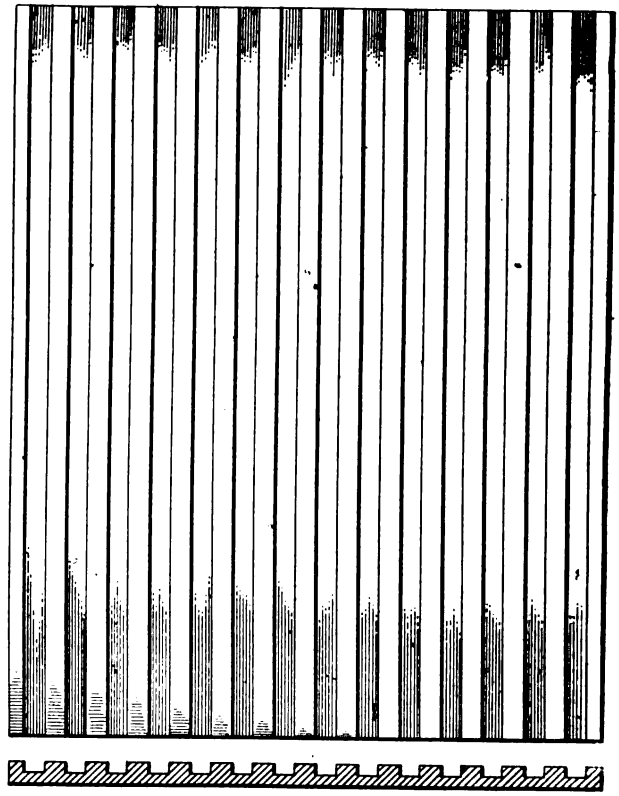


Fig. 1—An Exide non-acid wood plate-separator. On the bottom is an enlarged section.

boxes, and loss of charge are a few of the troubles that at one time or another may beset the battery user. The list sounds a fairly formidable one, but battery progress has been so rapid that, with the exception of sulphating, buckling, and occasional terminal troubles, all others are more or less absent from present-day batteries of repute. The three defects referred to, however, can usually be traced to ill-usage, and, since the best batteries are liable to be so attacked, some information on the subject seems necessary.

Buckling, or bulging, of the plates is almost unknown in well-managed installations. It may be caused by too rapid a discharge, while a very sudden large discharge will tend to drive the paste right out of the plates. Again, if too large a charging current is used for the area of the plates, buckling is very likely to ensue, and very rapidly, if the positives are in a bad state. Short-circuiting, due to plates touch-

Digitized by Google

ing, is then established and paste lost, and the battery capacity seriously diminished.

Buckling is due to unequal expansion of the plates, and may occur under the best of circumstances if the makers have not given the plates the correct form, and, further, so designed them that the expansion and contraction of the paste on charge and discharge is provided for.

A starting battery works under abnormal conditions, exceedingly heavy and rapid discharges being demanded from it. Buckling and short circuits would then inevitably ensue if proper precautions were not taken to avoid it, and it is found necessary to separate the plates by continuous one-piece separators of the type illustrated in Figs. 1 and 2. The plates and separators are tightly packed together and form a semi-solid mass. The grooving of the separators permits free acid circulation and rapid escape of the gas generated, and, in conjunction with the porous ebonite diaphragm, prevents buckling and loss of paste.

Sulphating.

Sulphating is perhaps the most prolific source of accumulator trouble, and, together with local action, occurs chiefly during idle periods. On this account, then, all cells should be kept in regular service and as fully charged as possible, for it is found that the best results are to be obtained when the system has been so designed and constructed that the battery is normally kept well charged without excessive over-charging. Bad sulphating is indicated by the chocolate color of the positives turning whitish grey in patches all over the surface, or by a red scale appearing as mentioned previously. There should always be a marked difference in color between the positive and negative plates if the cell be in order, and, if not, immediate examination is necessary.

Bad sulphating results in the destruction of the cell, since the paste falls out; buckling and shorts may also take place, and the grids usually become rotten. The causes may in general be traced to the use of an incorrect acid solution, overcharge or too rapid discharge, or to the fact that the cells have been left standing idle when in a partially discharged condition. The cure for a partially sulphated cell is to subject it to a lengthy overcharge at a moderate rate. Such is only to be undertaken at a charging station, and, since the active plate area is much reduced by the sulphating, the charging current must be only a fraction, say one-third to a half of the normal rate. The process is a tedious one, but must not be hurried or the positives will be injured.

Very badly sulphated plates are covered with an inert skin of white lead sulphate, and it is usually cheaper to replace them than to attempt a cure.

A cure is sometimes effected by cleaning out the cell. After a good charge, the plates are removed and the white deposit scraped off the positives with a wire brush, the plates meanwhile being washed with electrolyte. That in the cell will suffice, and the plates may then be reassembled in new electrolyte and the batteries charged up.

It is important to note that, during the cleaning process, the negatives must be left in the acid, otherwise they will be injured by exposure to the air. Buckled plates may at the same time be restraightened by pressure between wooden blocks, but not under any circumstance by the aid of hammering or the paste will be removed.

Many methods have been proposed for the restoration of sulphated cells, and, while not advocating any in particular, one method is worthy of note. The damaged plates are charged at normal rate for a period of sixty hours while placed in a solution of pure sodium sulphate, made by dissolving 2 pounds of sulphate in one gallon of water. After this charge, the solution is replaced by acid electrolyte of the correct strength, and, after a preliminary charge and discharge, the cell is said to be ready for service once more.

To Avoid Sulphating.

The complete cure of a sulphated cell is always a doubtful matter, and, since sulphating may be avoided by the exercise of a little care, the following hints may be of service: Fully charge a battery that has to stand idle for any length of time, since local action and sulphating occurs chiefly during idle periods. To keep a battery in condition and ready for service, give it a freshening charge at least once every two months, and a thorough charge until all cells gas freely before placing it again in service.

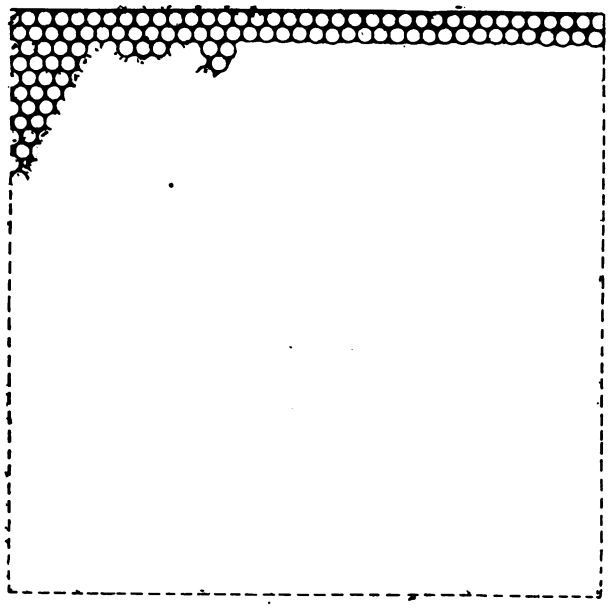

Fig. 2—A porous ebonite plate-separator, section only of pores being shown.

It should be possible to perform this operation at home, for the dynamo can always be used for charging purposes, the car engine running light for the purpose. If the cutting out speed is such, however, that it is necessary to race the engine, the batteries had better be put out of commission altogether for the time being, unless the local garage can undertake the charging or an apparatus is available. Never use a battery that has been standing idle for a considerable period without first giving it a thorough charge. During long idle periods disconnect all wires to avoid leakage through the car wiring. Avoid heavy working immediately on replacing the battery in service. To decommission, or lay up, a cell, syphon out the acid after a full charge, and then, after filling the cell with water, short circuit it to cause it to discharge. The cell may be left in the water for a day or two, and then the plates taken out and washed and well dried, and afterwards stored in a dry airy place.

The acid is drawn off first to preserve its density and to prevent the formation of lead sulphate on the plates. Small cells are frequently sent out with the

Digitized by Google

plates formed but discharged, while some makers send the cells out filled with water.

Burns and Acid Stains.

It is always advisable to keep a bottle of ammonia handy when working with batteries, for the application of strong ammonia solution to clothing neutralizes the acid and prevents a hole from being burnt in the material.

Dilute ammonia, or, failing this, washing soda or lime water, must be applied to the hands, etc., if acid accidentally reach them, and, if a splash enter the eye, wash with water, warm if possible, and then use a drop or so of olive oil. If olive oil be not available immediately, use any oil that is handy—engine oil, for example, answers better than nothing.

SPARK COIL REPAIRS.

Broken Insulation and Loss by Rewinding—An Instrument for Ignition Testing.

BY JAMES F. HOBART, M. E.

When you get into trouble with a spark coil it is about as good a way to send the coil back to the factory where it was made and have repairs made there but occasionally there are times when repairs are needed "day before yesterday" and sending to the factory is out of the question unless another coil is substituted. And this is a very good way, too, but sometimes even that will not answer, and the "know-how" of making coil repairs becomes worth a good bit of money to the garage man.

Repairing an ordinary spark coil of the make and break variety is a pretty easy job for you can take the coil down and put it together again, winding and all, without much trouble. But when you attempt to repair a secondary winding of an induction, or jump coil, then your work is cut out for you and you will earn your wages if you succeed in making the needed repairs.

But keep one thing in mind: After the winding of a coil is removed and wound on again, the coil never will be as good as it was before unless new wire is used for the rewinding. The reason for this is: Each time a wire is coiled or uncoiled the bending back or forth hardens the wire, increases its resistance and correspondingly cuts down the efficiency of the coil. Were it possible to anneal the wire after it was unwound from a coil, the increase of resistance through bending would be prevented and the coil would be as good as ever, after the winding was put back again.

In "wipe" coils and in the primary winding of "jump" coils, there will be but little loss through winding and rewinding the wire, but in the secondary coil there is a good deal to be lost by bending the wire back and forth in the winding on and off. In some coils where the wire is used bare and separated by means other than by insulation wound upon the wire, then it is possible to anneal the wire after it has been removed from the spools, but, believe me, you will do well not to "monkey" with one of those secondary coils wherein the convolutions are separated by air space instead of insulation. Even if you could get the wire off in good condition you could hardly rewind the coil again so it would be of much use without the use of special machinery similar to that upon which the coil was originally wound. To be sure, if you have rigged up for secondary coil winding then you can do it as well as the maker provided you know how.

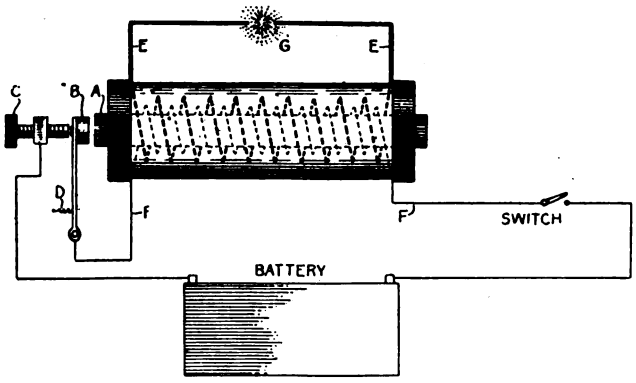
Usually the chief trouble with a "wipe" coil lies in the breaking off of the inner wire. It is often possible to dig into one end of a coil of this kind, bring out the broken wire, splice it and then return the wire to its proper place after repairing the insulation thereon. By lapping and soldering the No. 18 or No. 16 wire used in a spark coil it can be wound back by omitting one turn or a part of a turn and if you are too busy to mend the insulation by winding in thread until the bare place along the joint is covered, you can fix it very quickly by winding on a bit of paper string. As the string is wound on, give it just turning enough to untwist the paper strip so it will lie flat and thin on the wire, but it takes up lengthwise space on the splice very quickly. A rub with shellac after the paper has been wound on soon makes the wire ready to be wound back into the coil again. Be very careful in doing this that you do not break the insulation. Never use a metal tool in pushing the wire back into place in the coil. Use soft wood or a bit of celluloid or hard rubber and make very sure that nothing is torn or broken during the operation.

When you are given a jump spark coil to repair spend a little time in finding out the cause of the trouble before you begin to take the coil to pieces. If it is a mere break of the wire, either of the primary or the secondary winding, it will not be a very bad job to make repairs—unless you do other damage—but if the winding seems intact then look to the condenser before tearing up the coil.

The condenser consists of sheets of tinfoil separated by sheets of paraffined paper. The foil sheets are divided into two equal packs, each sheet an inch or so longer than the strips of paraffined paper between the foil sheets. Half the foil sheets project beyond one end of the paper strips and half the foil sheets project at the other end of the paper, alternate sheets projecting to right and left through the thickness of the condenser.

It is well before disturbing anything else, after you are sure the coil wires are intact, to disconnect the condenser, connect it temporary with another coil and see if the other coil works well with this condenser. If it does not there is probably trouble in the condenser. But if the new coil works well with the old condenser then just attach another condenser to the coil you have under repair and see whether that coil will work with the new condenser. If it does, and the new coil won't work with the old condenser, then you have pretty good evidence that something is wrong in the condenser and not in the coil.

Having made sure by several tests that the condenser is at fault, dig down into it and be very careful that you do not tear any of the strips of tinfoil. Use a dull knife or a bone letter opener for straightening up the pieces of foil where they have been clamped together outside the paper strips. Don't try to remove the foil until each strip has been gently worked loose from the paper.



As soon as you get three or four of the strips of paper free, examine each one very closely. Hold it between your eye and the light and see if you can find any holes in it. Just the merest pinholes if there be any. If many of these holes are found then you have discovered the probable cause of the trouble with that condenser. It has been broken down—perforated—by internal discharges and instead of acting as a spring, so to speak, for the electric discharge at the instant the circuit is broken,

Digitized by Google

the damaged condenser lets the electric discharge right through and instead of acting as a sort of shock absorber the faulty condenser is an actual by-pass for current and robs the coil of most of its power.

Sometimes the trouble may be cured by coating the slips of paper with another coat of paraffin. Dip each strip of paper separately into melted paraffin and then hang to dry or cool, in a warm place, heated enough to make sure that the superfluous paraffin drains off before it freezes. The paper will be of little use if it is lumpy with paraffin. It is a tedious job to recoat condenser paper in this manner. The paper when originally coated was in large sheets and the labor of coating was therefore much less. But with patience it can be done, each sheet being hung up to drain and dry by means of a pin thrust through one corner and suspended from the pin, in the oven or dryer, in such a manner that the paper strip can touch absolutely nothing save the pin which supports it.

It probably will be cheaper to procure new strips of paper and to discard the old ones. But if you do this, do not lay hands upon the first paper you get hold of. The paper for condensers must have been tested out for conductivity. Some kinds of paper don't insulate much better than thin strips of German silver, so great is the difference in the resistance of various kinds of paper. In fact, paper varies in resistance nearly as much as slate, and that substance should never be taken for switchboard use until it has first been thoroughly tested out and found to be of high resistance. And same with the paper.

Sectional View of a Jump Spark Coil.

Every condenser, when stacked up, with the pieces of paper between the sheets of foil, should be tested for resistance before the condenser is closed up and finished. Sometimes the pressing of the parts together breaks down the insulation and instead of there being thousands of ohms resistance between the terminals of the condenser there may be a short circuit or a very low resistance which breaks down under tension when the condenser is operated.

It is well to first test a condenser for ohmic resistance before taking it down for examination and repair as above noted. The use of the Wheatstone Bridge upon condensers and many other pieces of electric apparatus will often save a good deal of work and search in the wrong direction. Wheatstone Bridges are rather costly instruments and not every automobile repairman feels that he could afford one, but you can make one and the writer has one which he built several years ago and it has been in use since without requiring a moment's repair or adjustment. The writer has complete working drawings and instructions for building a good Wheatstone Bridge and if you desire you can arrange through the editor for the use of the drawings and instructions.

A good Wheatstone Bridge, applied to electric circuits about automobiles, often enables obscure but vexatious leaks and short circuits to be located and corrected with very little trouble. These instruments are invaluable for testing coils, wiring and suspicious spark plugs, etc.

Ten to one that with the terminals of the coil all right, and the condenser in good working condition, the jump spark coil will be found to work well. But if it does not and does not give as good a spark as it should, then there is a strong possibility that the insulation has been broken down between some of the coils and that the spark, or a portion of it, jumps across there instead of continuing as current through all the winding. When this happens rewinding is about the only cure which you can be sure of.

The illustration shows a section view of a jump spark coil, also called an induction coil, high tension coil or secondary coil. It illustrates the primary and secondary winding on the core and the magnetic vibrator, also illustrating the flow of electricity from battery through the primary wire circuit. When the current flows from the battery through this primary wire wrapped around the core or bundle of iron wires, A, the bundle of iron wires become magnetized and draw the vibrator, B, away from its connection with screw, C. The moment this vibrator is drawn away from the screw, C, the circuit is broken and the bundle of wires, A, loses its magnetism, therefore the vibrator, B, is drawn back to screw, C, again by spring, D, but the moment the contact is made again, A again becomes magnetized and again draws the vibrator, B. This is repeated so fast the vibrator, B, simply buzzes. B is a secondary wire wrapped around the primary wire, F. The greater the buzz the greater the spark and more current consumed.

When this vibration takes place the current is induced into the secondary wires, E, by "induction," and this induced current is intensified, that is, the pressure is raised to such a high voltage it will jump the space at the point of the spark plug, as at G.

Tight Tire Valve Caps.

When a very slight leak is present in a tire one instinctively suspects the valve, and is disposed to screw the valve plug and its cap hard up with pliers. Eventually, on the road, when the tire has to be pumped, it is not easy to remove the cap if the pliers have been left at home. The cap can in most cases be removed with the help of a piece of string or a boot lace. The end of the string should be unravelled and slightly moistened. It is then rolled tightly round the cap in the direction the latter is to turn until it forms a hard ball two or three times as large as the cap. The extra leverage thus obtained will usually enable the fingers to start the cap moving, as the ball of string is much softer to the fingers and easier to grip. The roughening on the cap effectually prevents the string from turning on it.

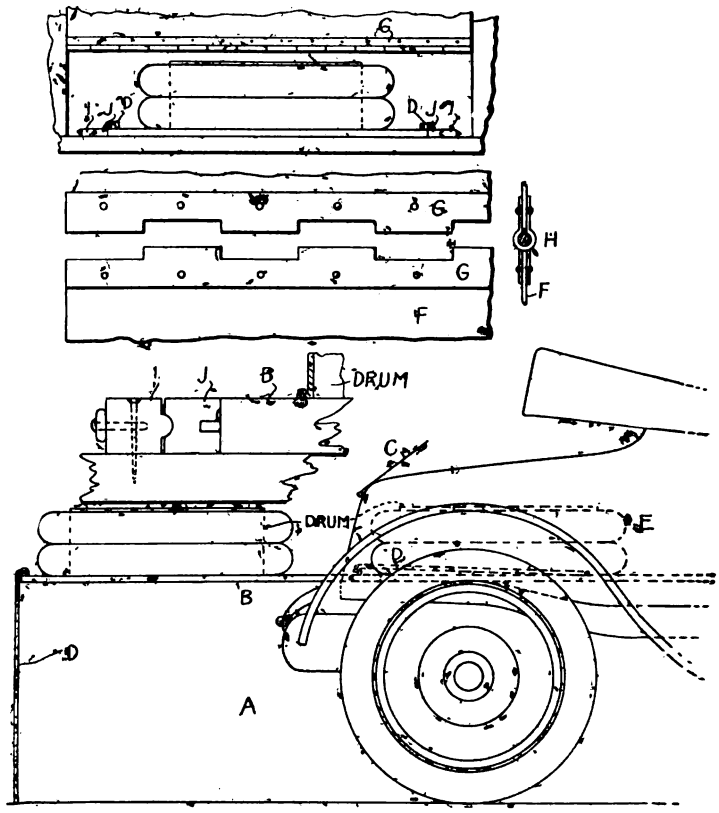
Laying Up a Car for Winter.

From G. E. Greenleaf, New Jersey.—Although the majority of automobilists continue to use their car throughout the year, in some localities the rigorous climate renders it necessary to lay up the car for a couple of months or more. This is not necessary for the most part in cars used under urban conditions, but to users who live in the country, a period of "jacking up" is unavoidable. If the owner is fortunate enough to possess a heated garage, the difficulty is not a matter of moment. For motors housed under these favorable conditions will be in no way disturbed by the advent of cold weather. During a stretch of unfavorable conditions, the car may be jacked up so as to relieve the tires from weight and a cover thrown over the whole machine.



To the motorist who has no heated garage and who does not care to incur the expense of storage, the problem is a more laborious one. The most important precaution to be taken is that of drawing off all water from the cooling system. After all this has apparently flowed out as much as possible, rock the car to force any remaining within the cylinders outside. After doing this it is a good plan to pour about a quart of denatured alcohol into the radiator and leave it there while the car is in storage. In order to remove all possible danger from fire, drain off all gasoline by the petcock in the gasoline tank and plug in the bottom of the carburetor float chamber. This will wash out the sediment collected in the gasoline system and leave it clean for the next supply. Inject about a pint of kerosene in each cylinder and turn the motor over with ignition off so as to thoroughly work it into the moving parts.

This treatment will tend to clean out carbon deposits.

Remove all oil from the motor crank case, differential and transmission, but do not rinse any of these with kerosene as the oil left on the metal will effectually prevent rust. In order to relieve the tires of all strain during their period of inactivity, the wheels should be jacked clear of the floor, the air pressure in each tire reduced to 10 lb. or so, and they should be washed with soap and water and carefully dried. It is important that the whole car be thoroughly washed before the storage period, for if any mud be allowed to remain it will stain the varnish. All bright parts of the car including the control levers ought to be given a complete coating of vaseline which will prevent tarnishing. When all has been completed a cotton cover or enamel cloth should be thrown over the machine and the owner may rest assured that deterioration will be very slight.

A Compartment for Tire Shoes.

From E. G. B., New York.—Spare tire shoes should have protection from deteriorating effects of the sunlight, rain and all weather conditions. The suggestion shown in the illustration will meet this requirement. It can be constructed at a low cost and applied to most every roadster of any make that has not a rear hinged door. By referring to the large view, A, this will show the convenience and operation of the tray, B, is pulled outward as shown in full lines, and the legs, or supports, D, at the end hold the tray as shown. The shoes are easily removed, or replaced, as they fit around a drum, which also keeps the shoes in place. Other articles can be placed in the drum, which is provided with a cover. When the door is closed the tray is entirely hidden in the rear of the car, as shown by the dotted lines, E. In the construction the writer has provided a tray large enough to carry a 32 or 36 inch shoe. In order to place this construction on your car, cut an opening in the rear of the car body, about 3 feet 8 inches by 12 inches. The piece of metal, F, cut out is used for the door and is riveted to a hinge, G. An end view of the hinge is shown at H. There are two beaded strips, I, which are screwed to the floor boards in the rear of the car, and are 1½ by 1½ inches by 3 feet 9 inches. The tray is made from two pieces of boards each 1½ by 18 inches by 3 feet 9 inches, glued together. On the outer edges of the tray are two

For Spare Tires.

strips, J, ½ by ½ by 3 feet 9 inches, glued to the edge of the tray, which are grooved out to fit the bead on the strips, I. A catch can be provided at the end of the tray to prevent it pulling all the way out. When pushing the tray back into place, all that is necessary is to grasp the sides of the tray and at the same time swing the legs, D, up, and they will rest on top of the tray near the edge, and the tray slides easily into place.

Protection for Rubber Mats.

Most of the wear on rubber mats comes at certain points, particularly where the driver's heels bear, just below the pedals. Some drivers who like to maintain the good appearance of their cars cover these parts with a piece of thick leather or aluminium matting. In the case of the near side running board, all the wear comes at two points (one in a two-seater), and when these begin to show signs of long usage it is worth while fitting a cocoanut step mat over these parts.

TROUBLE-DEPARTMENT

This department is intended as a "trouble clearing house" for car owners, dealers and repairmen. Inquiries in relation to marine motors will likewise be answered as they are of interest to car owners and others who use the two-stroke cycle engine.

Readers are requested to make criticism and comments or to freely discuss any subject of interest to the automobile industry, and to add information of their own experience in remedying troubles.

Inquirers are asked to give the fullest information in every case so that replies may be made intelligently, and thus be of interest not only to the inquirer but to others.

1688 **Valve Grinding.**

From A. J. Morel, Rhode Island.—I have an Overland model 79, 1914 car which has run about 8,000 miles, and I have not had serious trouble, but I will ask you a few questions. I have had the valves ground twice, and also the carbon burned out by oxy-gas process both times, and by a man in whom I have full confidence, but as I would like to grind and adjust the valves and tappets myself I would ask you the correct way, as plain as you possibly can tell me, why for instance, very shortly after having the valves ground, I find that there is poor compression in two of the cylinders? 2—The right wheel on my car seems to throw out grease, in spite of what I have done so far. Upon telling the garage man about the same, he told me to take out some grease from the differential, because I had too much. I thought there was a washer to hold grease, but he claims not. Can you advise me on this? 3—As my car has a grooved set of pulleys for the fan belt, I have been using those riveted piece belts, but as they are expensive, having a patent on same, can you inform me if I could not use different belts, and how and where could I obtain same? 4—My car is not equipped with a generator, although it has electric lighting system with Willard storage battery. I obtained a rectifier and it worked pretty well for a while, but now it does not seem to buzz as usual when charging, and I don't think it charges the battery right. Could you inform me if a small generator to keep the batteries charged would be practical and would it be a very expensive thing to do? Remember, I have no starter, but just keep the battery charged for lighting.

Reply.—1—It is a fact well known to those who really know, that the operation of grinding the valves involves a relatively higher skill than very many motorists realize. It is not unusual to find some one advising the use of a breast drill brace to rotate the valve on its seat. It is not unusual to see skilled mechanics who should know better use a drill brace and rotate the valve several times before lifting it to get some of the abrasive material between the valve face and valve seat. As a matter of fact such methods wear ridges which it is absolutely impossible to grind out, and which have to be pounded out by explosions during the running of the engine following imperfect valve grinding. If this operation is properly done the compression in every cylinder should be better—not worse. If there is a slot in the valve to take a screwdriver, nothing is better than a good heavy one for the purpose. For grinding use a very fine grinding paste, flour of emery, or the dirt which accumulates under a grindstone. Soap, oil or grease may be used to hold it upon the surfaces to be ground. After smearing these surfaces grasp the screwdriver firmly in the right hand (if right-handed) and the lower end of the valve stem in the other. Lift both screwdriver and valve an inch or two and bring them smartly down against the seat, give a twisting motion back and forth once, lift and repeat. This will avoid the formation of scores and ridges and is the surest and quickest method of grinding the valves. Care should be observed that none of the grinding material gets into the inlet valve chests or into the valve stem guides. A very small amount of abrasive material will be needed. When the valve seat and valve surface are dull all over evenly, the job will have been completed properly. 2—Your garage man advised you correctly. 3—The belts you are using are the best to be obtained for the purpose and considered by wise motorists to be well worth the price. 4—Many cars have been equipped with battery charging generators, usually driven by friction contact with the engine flywheel. To prevent discharging the battery through the generator windings a magnetic relay is absolutely necessary, for were the engine to be stopped without opening the charging circuit you would ruin not only the battery but the generator.

1689 **Oil and Smoke.**

From S. W. F., Pennsylvania.—I drive a model F, 1914 Ford, and am having trouble with oil and smoking. 1—The motor and inside of the hood are badly smeared with oil. It appears to be thrown by the fan or belt. Can you tell me where it escapes? 2—After floating down a hill and throwing on the switch it smokes very badly, perhaps for a half a mile or more. In fact it smokes more all the time than it should. I have put Perfection piston rings in pistons No. 1, 2 and 3 in one groove each. Plugs 1, 2 and 3 appear oily. I have used both light and medium oils but it don't make any difference.

Reply.—1—Probably through the front crankshaft bearing. 2—You may have overheated the engine and scored the cylinders and piston rings. This would cause excessive smoking as would an improperly adjusted or defective carburetor. The fact that the plugs in three of the cylinders accumulate oil would seem to indicate scored cylinders, which no type of piston ring would cure. Ford cars should not use light oil. Use medium or heavy.

1690 **Needs Overhauling.**

From A. A. Durham, Illinois.—I am having trouble with a Maxwell 2-3, 1910 model. The engine runs well enough when not pulling but when changing gear will miss two or three cylinders at a time and causes the car to jump. There is a continuous spark between the breaker box and the spark control lever when the engine is running fast. Should this occur, if not what is the cause of same and how would you remedy it?

Reply.—With a car running five or six years almost anything is liable to happen. Looks as if it needed a general overhauling and renewal of worn parts that would probably cost more than the outfit

Digitized by Google

would be worth. Probably the valve stems and bushings are so badly worn that the cylinders fill with air when you close the throttle to change gear. No continuous spark should appear, such as you describe. The magneto should be returned to the maker for overhaul and repairs.

1691 **Differential Types.**

From T. I. S., California.—1—After a heated argument with a friend, we decided to leave the question up to you as to whether all differential gears were of the same type. 2—And does the two wheels pull the same on a curve?

Reply.—1—Nearly all automobile differentials are of the bevel gear type, although some are of spur gear design. At least one differential is on the market which utilizes worm gear construction. Another operates without gears, a lever slidably mounted on a pin set at right angles to the axis of the axle serving to distribute the load evenly to the two half axles. 2—The maximum pull is the same to each wheel, with the exception of the friction in the differential itself. This frictional resistance may be little or much, depending upon its construction and condition of wear.

1692 **Magneto Trouble.**

From Walter A. Burns, Nebraska.—I have a Ford touring car, 1914 model, which has never caused me any trouble until a few days ago it suddenly stopped and would not start. I installed batteries and it started nicely and runs as well as it ever did, but when I switch to the magneto it does not run smoothly, and misses all the time. The trouble must be in the magneto, but I can't conceive just what the trouble is. The car has run a little over 3,000 miles and the magneto has been used for ignition purposes only, and therefore I don't think it is weak. I will be pleased to see a solution of the problem.

Reply.—If you will remove the small brush at the top of the magneto and clean the small hairy-like carbonized fibers from it you will probably have found and remedied the trouble. A peculiar thing about magnetos is that if used continuously they will last longer than if only used occasionally. We do not believe that Ford magnetos can be injured by using them for lighting as well as for ignition.

1693 **Descending a Hill.**

From S. D. Evans, Oregon.—1—Will it damage the motor, when going down a long, steep grade, to throw it in low gear, throw off the spark and assist brakes by the compression? I know it is all right to do it in high gear, but have been told it injures the motor if done on low gear and run the motor at a high rate of speed. 2—I have a 1914 Reo that I have driven about 6,000 miles. Recently I have had much trouble with water boiling on any little hill. I formerly had no trouble. A man with the same kind of car told me he had the same trouble, and found the slotted coupling between the motor and the generator worn and this allowed the spark to "lag." Mine has a play of about ⅛ inch. Is that enough to cause trouble, and do you think that the cause of the trouble? 3—Why does the motor lose power when the water boils?

Reply.—1—Probably not, unless you are foolish enough to run down hill at an excessively high speed. 2—Late spark causes excessive fuel consumption, and this in turn generating more heat in the cylinder the circulating water collects more heat than the cellular construction of the radiator will radiate to the atmosphere. Taking up more heat than it will give off means eventually boiling. One-eighth inch play is a whole lot. 3—Usually because the motor is so hot that the entering charge of gas and air is expanded, thus reducing the quantity of explosive mixture in each charge. If the motor is too cold the combustion is too slow, and if too hot too rapid, this being another bad feature, causing premature ignition at low and intermediate speeds unless the spark is considerably retarded, with loss of power as a result.

1694 **Storage Battery Ignition.**

From F. J. G., Washington.—In your answer to Geo. K. Weller—No. 1662—in the August number, you make the following statement: "One cannot start and furnish current for ignition from the same storage battery." This seems to be at variance with my experience. My friends have Apperson, 4-45 cars. One has a National magneto, low tension and coil. The other has changed to the Bosch dual system. Neither car had dry cells. Both are equipped with Gray & Davis lighting and starting system, Willard battery. The car with the National magneto and coil starts hard unless the switch is placed on the battery side. The other car is easy on either side, except in cold weather when it is easy on the battery. Both cars draw their ignition from the same battery that runs the starter. This I think is proved by the ammeter showing no deflection when the car is started with the switch on the magneto side, but 5 amperes if started when the switch is on the battery side. If I am in error I would like to know but we certainly use no dry cells.

Reply.—Both National low tension and Bosch dual ignition systems use separate ignition batteries of three cells. The current from the ignition battery is not used to operate the starter, there being in reality two batteries of accumulators, or dry cells, although all the cell containers may be in the same group, one three-cell container being wired to the battery side of the switch, and the others forming a battery for starting. As ordinarily looked upon by motorists, an ignition storage battery consists of three cells wired in series, these three cells of battery being in a container. If there were, say, eight of these containers, they could be wired in anywhere from one to eight or more separate circuits—one to eight or more batteries in fact—for all the eight containers may be in a single compartment in the car. These eight three-cell containers may be so wired, be there from one to eight circuits, that the generator will charge them all when up to speed, this method of wiring for charging being known as multiple parallel-series, in this case eight in parallel of three in series. The ammeter is placed in the ignition circuit and not in the starting circuit, as evidenced by the fact that it shows zero when drawing current for starting and 5 amperes when using current for ignition.

1695 **Driving Cramps.**

From Harvey E. Harris, Connecticut.—In the July number, on page 69, Mr. H. S. Scott writes, asking about chauffeurs' cramp. At this writing both

Digitized by Google

calves of my limbs are so sore I can scarcely stand on them. Does not seem to bother me any while driving, but when I go to bed it is then that the cramps start. Sometimes when driving any great distance there seems to be a slight cramp of the thigh, which I have always thought was caused by sitting in a fixed position. I purchased a rubber cushion of the pneumatic kind and think it relieves me somewhat of the cramp. Have heard of no accidents caused by cramp while driving.

Reply.—Cramps of the kind referred to are undoubtedly caused by sitting for some time in a confined position. The tendency is more liable to ensue in the case of an automobile than in driving a horse-drawn vehicle because of the necessity of keeping the body and limbs in practically one position, and also owing to the necessity of keeping the mind as well as the body fixed upon the work in hand. Fortunately, cramps while driving a car or after having driven one are not dangerous; they are merely unpleasant, and they are caused by lack of blood circulation, which may be more frequent when one has caught cold.

1696 **Gets a Shock.**

From Patoka Garage, Illinois.—Can you tell me what is the trouble with a Maxwell car, model 1911, Splitdorf low tension magneto system, old model Kingston carburetor? The magneto and coil were repaired at the factory. We get a good spark, but when touching the coil switch, while running, we get a shock both from the battery side and magneto side. We have changed the wiring with no results. The motor misses and runs better on the battery than on the magneto. I think the missing is the fault of the carburetor, but I cannot account for the shock received from the coil switch while running. Kindly advise me what the trouble is, if possible.

Reply.—With a car five years old one should not expect results possible with one of later design, even if it has not been run at all. The switch is undoubtedly defective. It may be a leak of high tension or secondary current, as it probably is, and is possibly due to an imperfect ground connection. The secondary circuit uses a part of the primary wiring to complete it, and if this metallic circuit is imperfect the resistance of the spark gap at the plugs will cause it to leak this induced current of high voltage and low amperage. You should equip the motor with a more modern carburetor, one with sufficient capacity to supply double opposed motors. As a matter of fact the old model D Scheblers and the early Kingstons give fully as good results with double-opposed motors as some later designs and types of carburetors.

1697 **Uses Too Much Oil.**

From Coy P. Smith, Texas.—I am making inquiry as to the Maxwell, model 35-4, 1913 car. This car has Splitdorf ignition, and Stromberg carburetor. The trouble is that it uses too much oil. A half gallon will not run more than 30 or 40 miles. Everything is in first class shape, piston rings, valves and everything, but still it uses too much oil. The grade of oil does not have anything to do with it at all. I have tried everything I know of, and would appreciate any help you might give me, or any suggestions. Probably some owner of a Maxwell 35-4 could suggest something. Anything that will help will be appreciated.

Reply.—As a remedy for excessive oil consumption our suggestion would be newly fitted pistons and rings, and probably reground cylinders, as we believe no other cure will be found efficient. Loosely fitting pistons, badly worn piston rings and scored cylinders may be looked upon either separately or combined, as the cause in approximately 90 per cent. of such cases. Manufacturers and repair shops equipped to do such work usually charge $10 per cylinder. This of course does not include disassembling and reassembling the engine.

1698 **Magneto Fails on Slow Speed.**

From Merritt B. Harmon, South Dakota.—I want your advice on a Ford car that I have here and cannot fix. The magneto on this car will run the engine slow, but when we speed the engine up it cracks like a cannon. If we switch over to four dry cells it runs fine. I have taken the engine apart twice, and found that the flywheel magnets rubbed on the coils. I put a piece of pasteboard under the flywheel to hold it away from the coils and then it cleared about the thickness of a blotter or a table knife. It will light 6 volt 6 candlepower lamps, but they are not bright as they should be. Please answer right away as I am anxious to get it fixed.

Reply.—Looks as if the magnets had worn through the insulation of the coils by rubbing against them. It may be that the magnets of the magneto are partially demagnetized. You have not the voltage that you should have, as evidenced by the dull lamps.

1699 **Ten Questions.**

From W. T. K., Connecticut.—1—I would like to know if the spark coil takes ½ ampere, how can I ascertain whether it is giving full result? 2—Does a voltmeter indicate this and what should be the voltage? 3—How can one ascertain the power of a Ford magneto? 4—Supposing a Ford car is making 10 miles or 15 miles per hour on dry cells, will a voltmeter tell whether it is up to standard, and if so what should be the voltage? 5—In working around the coil connecting with the dry cells (4) the man who put it on grounded the 4 dry cells through the magneto. Would this injure the magneto? 6—If a Ford car is running on dry cells, what becomes of the electric energy that is being developed or is there none? 7—Will you explain this matter? 8—I have one of those electric heating coils placed on the gasket of the manifold and carburetor. It runs to take about 4 amperes when ammeter is connected up with it. Is this as it should be? I have not been able to discover any great results as regarding easier starting. 9—With a master vibrator, should not all the coils show the same results? 10—If spark plug points are only 1/64 of an inch apart, what are the advantages or disadvantages over 1/32?

Reply.—1—On a dead short circuit it should take more than ½ ampere. We are wondering how you were able to accurately measure the amperage of the ignition current when using vibrating coils. 2—A voltmeter measures the voltage only. Might just as well try to measure the volume of a quantity of gasoline by means of a gravity gauge, as to attempt to measure voltage by an ammeter, or amperage by

Digitized by Google

a voltmeter. 3—By trying it out on a bank of lamps, using the battery for ignition, would be one way. But what would be the use of such a procedure, providing of course you were prepared to install new magnets, coils, etc. 4—You could connect a voltmeter across the two leads and short-circuit the magneto. We advise you not to do it. The Ford magneto generates about 12 volts ordinarily. 5—A crazy thing to do. It might not injure the magnets or coils. It certainly could not do either any good. 6—None generated unless the circuit is short-circuited. 7—Metallic circuit must be at least partially completed, as through the filament of a lamp, before current will flow. 8—We were never sufficiently interested in the device to make any investigations or experiments. We are not surprised at results obtained. 9—If coils are in proper condition and of same strength and construction—not short-circuited—yes. 10—One-sixty-fourth may be so close that carbon will accumulate and short-circuit, or the gap may be so wide that the spark will not jump it. One-one-hundredth of an inch is the thickness some magneto manufacturers advise. A thin dime is frequently used for a gauge. Battery ignition, for best results, takes a slightly wider gap than magneto.

1700 **Re-Boring Cylinders.**

From Frank Erxleben, Indiana.—1—In reboring cylinders, which is the most economical and also quickest way? Of course, there are no pistons of the same size and you have to turn out from an average 2½ to 5 inches. 2—Is there a collapsible core box on the market for the different sizes?

Reply.—1—The very best way is to have them reground in a cylinder grinding machine, such as the Heald. In this case it is necessary to take out a minimum amount of material and stock piston castings, or those sent out for repair or replacement, have sufficient metal to make a proper fit for the slightly enlarged bore. 2—Never heard of any such core box and do not see how such a device could be made of any practical use.

1701 **Car Stops.**

From Louis Benson, Michigan.—I have had considerable trouble with my car for some time. It is a Patterson, Model G, 1911. I have had trouble with my engine. I sent my carburetor away and had it all rebuilt but it did no good. When the engine starts it will only run for a short time and then stops, and when it stops it seems to throw the gasoline out through the carburetor. Now I have sent my magneto and spark coil away thinking that the trouble may be there. When I test my plugs with a screwdriver, Nos. 1 and 2 plugs seem to fire all right and the engine will slow down, but when Nos. 3 and 4 are tested in the same manner, the engine will not slow down. I think the trouble may be in the valves, and I wish you would give me an idea how to time the valves.

Reply.—If the carburetor is the one which was used when the car was new you cannot expect it to operate satisfactorily with the present heavy and hard-to-vaporize gasoline. The throwing of gasoline through the carburetor indicates too lean a mixture—too small a proportion of gasoline vapor to the air. You probably have the Nos. 3 and 4 cylinders wired improperly. It is possible that you have not the correct firing sequence, which is probably 1-2-4-3 or possibly 1-3-4-2, although the Nos. 1 and 2 cylinders are probably wired correctly. As to the timing of the valves those in Nos. 1 and 4 cylinders should open and close at just the same relative position of the flywheel, while Nos. 2 and 3 should both open and close alike, and exactly one-half revolution ahead or back of Nos. 1 and 4.

1702 **Misses on High.**

From T. A. H., Iowa.—We have trouble with our car missing fire. It is an Apperson four 1912 or 1913 model with Rayfield carburetor. It fires well on low speed, but when pulling hard, or when shifting from high to intermediate, it will begin to miss badly. Raising the choker a little helps it some till it is well heated when it must again be closed. We are using Standard gasoline. Higher grade seems to help it some, but does not remove all of the trouble. We think the ignition system is working quite well. What can be done to improve the working of the car?

Reply.—It is rather unusual for a motor to fire regularly on low engine speed and give trouble on high engine speed. From the wording of your query we are not just sure whether you refer to low car or low engine speed. It is further confusing to us to read that it misses when pulling hard, etc. From which you should observe that it is frequently hard to answer inquiries which tell us what we want to and should know, and unsatisfactory to all concerned when the inquiry itself is not clear. Broadly, however, we have to say that you will have to install a carburetor of more modern design before you can hope to have the engine fire regularly at the usual running engine speeds. You probably will have to re-bush the inlet valve stem guides to prevent leak of air into the mixture at low engine speed. Other than this we are not able to give you any further information.

1703 **An Offensive Noise.**

From a Reader, California.—I have a 1913, 25, Studebaker car. The car has never given me any trouble. A short time ago a peculiar noise developed in the motor. It sounds like the vibration of a sheet of tin when you shake it. The noise is sometimes louder at times than others. I have had all connecting rods taken up, new piston pins put in, and also new push rods and bushings. Still I didn't get rid of the noise. I have been told that it is a piston slap and the sound is very similar to the slapping of the hands together. The noise comes from the inside of the motor. Can you suggest any remedy for the difficulty? In fact, what is a piston slap, and what remedy is there and what is the cause? The car runs like a top outside of this annoying noise.

Reply.—If the hole through a piston in which the piston, wrist or gudgeon pin goes, is not absolutely at right angle to the bore of the cylinder, the upper end of the connecting rod will alternately hit first one side of the piston and then the other. If the piston is very loose and has insufficient bearing above the wrist pin, it will flop around the cylinder. Either of the above conditions will cause what is known as a piston slap. A sure indication of the former is a bell-mouthed condition of the crank pin bearings—small at the center and larger at the ends. The remedy is new and more perfectly machined pistons to replace defectives.

1704 **Magneto Trouble.**

From A. R. Tolhurst, Ohio.—1—I recently had a Ford car in for repairs that was very hard to start on the magneto, but when started would run fairly good until the lights were switched on, when it would almost stop. A magnometer test of the magneto showed a reading of very good, without the lights on, and very poor when the lights were drawing, although the lights burned brightly. Thinking that perhaps the magneto had drawn too far away from the coil assembly, I took the motor out and found that the magnets on the flywheel were rubbing against the coils instead of having a space between of 1/32 of an inch. I corrected this trouble and found that the magnets had plenty of magnetism, rang out the coil assembly, using two No. 6 dry cells, connected in series, with a door bell, and coils apparently were all right. After putting the engine together, and making sure that the spark plugs and wiring and spark coils were all right; carburetor in good condition; valves ground in and carbon removed; entire commutator and wires new, the car still gave trouble about starting on the magneto. I connected up the dry cells and tried both close and wide adjustment of spark coils but with no better results, and the engine still would not run good when the lights were switched on. The best results were obtained with the spark lever about halfway of quadrant, advancing or retarding from this position causing the engine to fire very irregularly, but not confined to any particular cylinder. I set the gaps of the spark plugs closer together and tried every expedient known to me, but am at a loss to locate the trouble. 2—Was my system of ringing out the coil assembly with dry cells and door bell correct? 3—If a coil was defective, insulation burned through or short-circuited in any manner, would the bell have rung when connecting wires were held to opposite sides of coil connections? 4—What, in your opinion, is the best, simple and most practical way of testing out the Ford coil assembly to find defective coils?

Reply.—1—It is probable that you were using lamps of too high candlepower, the result being that there was insufficient current left for ignition. With the insulation rubbed through your coils may have been partially short-circuited. 2—Your method of ringing out the coils did not show you anything except that the wiring was not broken. 3—Yes, why not? 4—Try a set of coils from a car which you know is O. K. A galvanometer is the proper instrument, but expensive and usually not easily obtained.

1705 **Battery Repair Work.**

From G. A. Bernard, California.—1—Why short-circuit a shunt wound generator to prevent its burning out when the battery is removed from the system? 2—Does this hold good with a compound wound generator? I should say, shortcircuit its shunt field. Please explain in full. 3—Can you suggest a simple means of constructing a hydrogen generator and burner to be used for lead burning in battery repair work, or some other suitable means of effecting the same result on a small scale?

Reply.—1—Because, with the battery removed, all the current generated will pass through the shunt to the field coils. 2—A compound wound motor being a combination of series and shunt connection, the voltage would not run so high as it would with a shunt wound generator at high engine speed. 3—For lead burning hydrogen gas is generated by the reaction of sulphuric acid and zinc. If you have some means of controlling the submergence of the zinc in the acid, such as a water sealed gas holder with the zinc suspended from the top of the floating inverted part, it might do the trick. We do not advise that you do any great deal of experimenting with such a device unless you do it in the outer air, rather than within a building, for hydrogen gas with the correct amount of oxygen as in the air, is very explosive. For a burner you need a piece of brass with a small hole through it fastened into a small strong rubber tube.

1706 **Water in the Cylinder.**

From A. Neumann, Wisconsin.—The writer some months ago purchased an 18-foot launch, equipped with a 6 horsepower, two-cylinder Detroit engine, the boat being purchased from the Detroit Boat Co. These people have never furnished instructions covering the operation of the engine and I do not feel like asking them for any more. The trouble seems to be that the water gets into the lower cylinder somehow, short-circuiting the spark plug every little while. I am using Reliance spark plugs, but even these seem to short-circuit. From this meager description can you advise what the possible trouble is?

Reply.—Water probably leaks into the cylinder through a sand hole in the cylinder casting which permits water from the water jacket to seep into the chamber communicating with either the inlet or exhaust port openings, this being the most usual constructive defect. Of course it is barely possible that you have installed the engine with an under water exhaust, the top of the cylinder being slightly lower than the outside water level. You can be quite sure to find the fault in either a defective cylinder casting or an improper installation. Water in the cylinder, except in minimum amount, will short-circuit any make of spark plug, or any electric ignition system, battery or magneto, jump spark or make-and-break.

That Magneto Trouble.

From Reader, Rhode Island.—Noting that H. P., Delaware, No. 1665, in your September issue is experiencing trouble with his Remy magneto, I am contributing a few suggestions. In the first place the answer to H. P.'s question is not correct. It is stated in the reply that the magneto is not a low-tension instrument. I am very positive that the Remy Electric Company did not manufacture anything but low-tension magnetos up to and including the year 1913. The magneto has but one winding, a coarse or primary wire, and the electricity generated is therefore low-tension. This low-tension or primary current is intensified by a coil, and the coil is therefore utilized to intensify both the magneto and battery current, not used merely when the source of current supply is the battery.

Unless I am mistaken, the trouble experienced by H. P. is in the contact points of the cam housing or breaker box. If he will carefully examine the components he will find that one is a fixed and the other a movable member. The first named is adjustable by means of a knurled nut or screw on the outside

Digitized by Google

of the cam housing. The other point is pivotally mounted and is moved when the cam, integral with the armature shaft, comes in contact with the movable lever. This lever should move freely and easily. The contact points should be perfectly clean and all foreign elements such as a red colored dust displaced.

The adjustment of the points on the Remy R. D. type of magneto, which I presume is the magneto used by H. P., should be so made that the maximum break is between .025 and .03 inch. If the motor misses with the spark retarded and the skipping is more pronounced at low rather than high speeds, the contact screw should be screwed in a notch at a time. The adjustment is easily made, and if H. P. will slightly alter the adjustment and note results, it may assist him in locating his trouble.

The test for the ground wire, as suggested in your answer, is best made by removing it entirely, making sure that if it be not entirely disconnected both at the magneto and ground connection that the free end does not come in contact with any metal. To stop the motor after making such a test, make a connection between the ground wire connection of the magneto and any metal part of the motor by using a piece of metal, a screwdriver blade, for example.

It will be well for H. P. to carefully examine the gap of the spark plugs. This is a point generally overlooked but it is very important. Different motors require different gaps but .025 or .03-inch is held by the Remy Company to afford the best results. If the motor misses when running idle or pulling light, the gaps should be increased. If the engine misses when pulling heavy at slow speeds, decrease the gaps. It is equally important that each plug have a similar gap.

It is doubtful if the Oldham or other coupling taking the drive for the magneto, be worn enough to cause a late break of the contact points, though an instance of this kind came under the attention of the writer a short time ago. The advance of the spark lever is another factor that should be considered by H. P. I trust the few suggestions will be of service and will be pleased to hear further from him.

Has a Good Car Record.

From R. J. Roe, Illinois.—I drive at present an eight-cylinder Cadillac. I bought it against the advice of numerous friends who said that they wouldn't oil, the cylinders would wear oval and lose compression; they would eat up tires, use too much gas, and about a hundred other reasons were advanced why the car was a failure. Now let me straighten things out. The car has gone 6,575 miles at this writing. I've averaged 10½ miles to a gallon of gasoline, which I buy in 100 gallon lots. The oil runs about 525 miles to a gallon. Not half bad to my notion, and I've had absolutely no trouble of any kind with the oiling system. Now the tires are Goodrich Silvertown Cords and I'm yet to have my first puncture. Surely a good record, and they look good for at least 10,000 miles and maybe more. The only trouble was with the Delco distributor. One Sunday the engine stopped dead, and no amount of cranking would get even a cough out of one of those eight cylinders. Upon careful investigation I found the platinum points were frozen together in the breaker. A little sandpapering put them in condition to get home again. Then I took them out and ground them smooth on an oilstone. I only wish everyone had as few troubles with their cars as this one has given.

Synchronous Firing.

From E. E. Larson, Iowa.—There are many drivers of Fords and other cars using individual spark coils that have trouble in getting synchronous firing. The object of this article is to show the cause and the remedy. Fig. 1 shows a vibrator set on a new coil. You will notice that the armature, A, lies very close to the core, B. Fig. 2 shows the

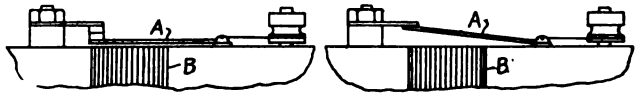

Fig. 1. Fig. 2.

same set with the contact points badly worn, thus doubling the distance between the armature and core, causing the magnetic pull to be decreased to one-fourth that of Fig. 1. It is obvious that if the contact will brake at all it will do so later than in Fig. 1. By examining the coils in a Ford car that has been used some time you will never find the armature an unvarying distance from the core because some points burn quicker than others.

One remedy is shown in Fig. 3. The bar, C, is bent as shown. A better way would be to make the insulator, D, out of thin sheets and remove one each time the points are dressed. I hope this will correct

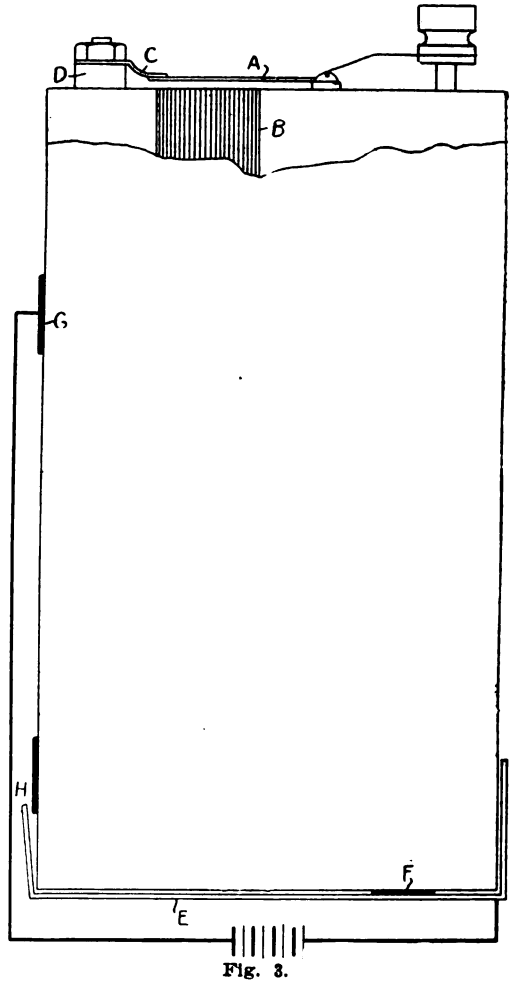

Fig. 3.

the fallacy held by many that synchronous firing can only be secured by the use of a master vibrator. Fig. 3 also shows a handy way to test coils. A sheet of brass, E, is bent as shown and placed in contact with the ground, F, when the wire from the battery is in contact at G, the spark will jump at H.

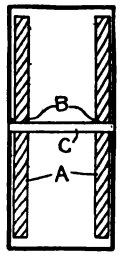
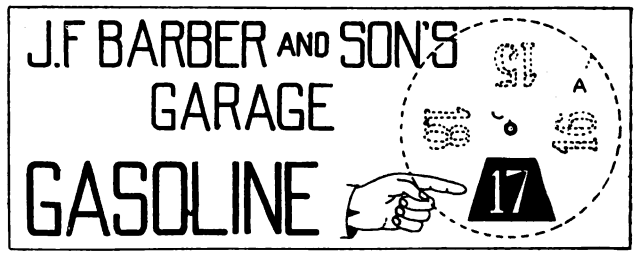
Painting the Car.

From H. A. Kidwell, Indiana.—To the carriage and automobile painter who wishes to turn out first class work, that will have a beautiful surface free from specks and dirt, I suggest that he will take great care in preparing the job for paint. Very often you hear a painter say, "I wonder where that dirt came from; I had the gear clean, a clean duster, my brush in order, and I was very careful in removing grease. Also I had the doors and windows closed against the dust." And yet he wonders. In my opinion no paint shop is complete where there is no study of harmony and beauty. Let the painter remember that the only way to bring out a handsome appearance is to start right and he will have little trouble. I will now give my best method of preparing the job for paint. This work should be done outside of the paint room, so that no particle of dust be allowed in the room. For cleaning the gear I have found a piece of burlap answers the purpose best. For removing grease or oil, take a cup of gasoline, using a stiff brush, not necessarily a new one. Be sure and clean thoroughly around the belt heads. These places should be thoroughly cleansed. It is not necessary to remove the body of the machine from the gear, but the fender and hood should be removed. After giving the gear a good washing, rub down with pumice stone. A second washing and dusting and the job is ready for the paint room. The body should be taken through almost the same process, rubbing it down with pumice. Above all see that there is no loose paint or varnish left on the job. Before putting on the lead coat, look around and you will no doubt find places where the paint has scaled off. Touch these places up with primer, and let the job stand four or five days.

How to Repair a Hand-Operated Horn.

From E. G. B., New York.—The hand-operated horn is really an outcome of the electric diaphragm horn, having the same essentials with the single exception of the means of imparting motion to the diaphragm. Often times the tooth in the center of





Showing the Hand Horn.

the diaphragm will become so worn that when the plunger handle is pressed downward the sound is rather faint, and one will try to imagine what the trouble is. This trouble is illustrated in the drawing. The pressing down on the plunger, A, revolves the toothed wheel, B, the teeth rapidly passing over the end of the tooth, C, which is secure in the center of the diaphragm, D. If the end of tooth, C, is worn off, the teeth on wheel, B, will never strike hard enough to produce the proper sound. The writer will give two simple ways of repairing the tooth, C. The small view, E, represents the worn tooth, C. Take a small piece of steel, F, drill a hole through the tooth as well as through both ends of the steel, and insert a pin, G. This lengthens the tooth to give the proper sound. The second repair is by the use of the post on a worn out dry cell battery, which is shown in view H. Remove the screws, I, shown in the larger view, and take out the diaphragm, D; then remove the worn tooth, C. Now with the battery post, J, put the screw end through the diaphragm, D, and then place the post screw head, K, on to hold it in place. These repairs can be done in a few minutes and will give the same sound as before.

Gasoline Price Signs.

From S. P. C., Rhode Island.—The price of gasoline fluctuates, compelling the garage and repair

For Price Variations.

shop to change their prices, raising or lowering according to the market. Many garages are content with painting the price on a piece of cardboard and attaching the display to the side of the building or sign. Other shops employ a blackboard utilizing chalk for marking up the figures.

These methods do not make for neatness or convenience and many times the figures are not easily read by the passing automobilist. The arrangement shown in the accompanying illustration not only saves time when changing the selling price but is attractive. It consists of two circular pieces of wood, A, about 18 inches in diameter. These are painted white or black and on their face is painted in black or white four prices, the figures being spaced equi-distant.

The center of the discs are drilled as shown in the sketch at B in the sectional view and the dials are supported in the sign proper by a rod, C. As the discs can be totated it is a simple matter to move them so that the desired figures will show in the opening of the sign. For example: If the price of the fuel is raised one cent by the producer, the dials are rotated clockwise until the desired figure shows in the opening. The arrangement displays the price on either side of the sign and two or more sets of dials are made up to care for any possible variation in the retail price. The dials can be painted from 11 to 14, 15 to 18 and 19 to 22, inclusive. If an illuminated sign be desired, the dials can be constructed of an opaque material and the figures painted on or made of glass with a black background.

Cause of Serious Trouble.

From a Repair Man.—Not long ago I was sent to examine a car which was suffering from a peculiar complaint. There was no clearance at all between the valve stems and the valve tappets. This had, of course, resulted in bad starting, overheating, loss of power, and other troubles. The owner could assign no reason for this trouble, but I eventually elicited from him that the cylinder heads had been removed to decarbonize the engine. The engine was of the detachable head type, with the valve chambers, etc., cast in one piece with the head. I soon discovered the cause of the trouble to be that the old cylinder top packing had been discarded, and a new one cut from jointing material that was thinner than the original packing. When this had been inserted and the joint nipped up it had caused all the valve stems to come lower down and rest on the tappets, thus giving rise to the conditions mentioned above. The owner had not tested the clearances after reassembling the engine; this should always be done even when the old joint washer is used.

A Help to Starting.

He stopped the motor and failed to get it to start. As he always carried a block of wood, which just clears the back wheel off the ground, he was able to get the momentum of the free back wheel to assist the intensity of the spark, for in the Ford this increases with the speed of the magneto. The jacking up of the back wheel also makes the work of turning the starting handle much easier. The reason for using a wood jack is to prevent the car jumping off the ordinary metal jack with its small base, an accident which has happened to him and others.

On all occasions when a preliminary turn or two of the starting handle fails to produce a spark after jacking up the back axle in the manner stated, always proceed along certain lines of investigation. The cover of the vibrator is removed, and it is noted if any spark proceeds when the handle is turned. If there is none, then the cause must lie between the magneto and the coil box. If altering the adjustment of the vibrator blade does not remedy matters, then an examination is made of the wire running to and from it for looseness of terminals, touching of copper ends and, of course, not forgetting the switch.

Throttling Down the Ford.

From R. S. Morey, Connecticut.—I wish to say in regard to statement in the August number, about throttling down the Ford car, that last summer by adjusting my carburetor carefully and having the motor clean, I was able to run my Ford car, with four passengers, on a level macadam road, at the rate of four miles an hour, on high, with the clutch fully engaged. I could do this any time I wished. Several times I slowed it down to three miles an hour, but it did not always pull steadily with that speed.

In Case of New Bearings.

After making new crankshaft and connecting rod bearings for an engine, a repairman may well run the engine light for periods totalling up to an hour or so before he will throw the burden of propelling the car upon it. If this running-in process be omitted for any urgent reason, the owner should avoid racing his engine; he should keep it well throttled down for at least a hundred miles, and observe extreme care in starting, gear changing, and the use of his clutch. Preferably, he should confine the work to short runs, giving the engine long rests at frequent intervals, so that any heat caused by the friction of "high spots" may be dissipated, until the microscopic projections have been smoothed down by gentle work.

To Steering Knuckle Bushings.

From R. Strehorn, Colorado.—I have owned a Ford car for the last four years, and being a machinist do all of my own work. I have often noticed mechanics in applying new bushings in the steering knuckles, put a jack under them, then get a punch or chisel and drive the old worn bushings out. I have also seen arms bent and sprung. The same applies when they put new bushings in, and I have seen bushings spoiled by being started crooked, and others spoiled by being too tight. I have invented a tool that does away with all this trouble. I have put in new bushings and taken out old ones in 15 minutes, without damage of any kind. In fact, it is impossible to bend or spring the arm. In removing the old bushing, the steel stem is put through the bushing, the 9/16 part fits in the hole in the bushing, the plain part being 1/32 smaller than the hole in the steering arm. The sleeve is placed on top of the arm, the hole in the same being 1/16 larger than outside of the bushing. The nut is put on the stem and tightened. This will pull the tightest bushing without any strain whatever being placed on the arm. In putting in new bushings the operation is reversed. If the bushing is too tight after starting, reverse the tool and pull the bushing out and file to fit. I think every Ford owner should have one of these tools, as these small bushings wear after a few months use. The cost of bushings from the Ford factory is only 10 cents each. It will cost at any garage to apply these bushings not less than 50 cents or $1.00. I would like to dispose of this tool to some auto supply house. It can be used on any automobile by increasing the sizes to suit the make of cars. I do not have this device on sale as yet and would dispose of the right to manufacture and sell to some enterprising supply house.

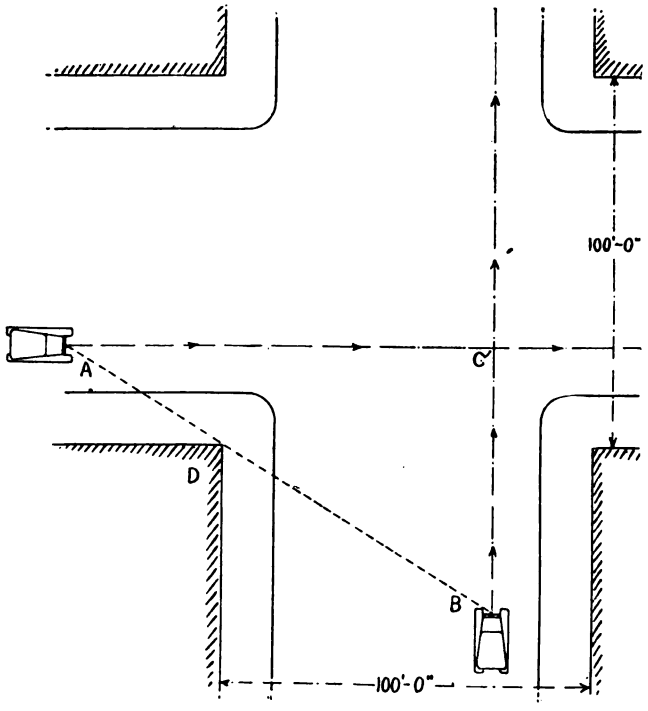
(Note.—Mr. Strehorn's address is Pueblo, Colo.—Editor.)

That Noise in the Buick.

From D. Bennett, South Carolina.—I notice in your September number complaint No. 1664 from Frank Revelette, Jr., Kansas, about the B-37 Buick. The noise is caused by worn bushings at the front end of the torsion member. There is a large ring with four bearings with bushings at the front end of the drive shaft housing or torsion member. It looks like a large universal joint. A new drive ring and four bushings will correct this man's trouble. He needs these parts: One part No. 30455 drive ring and four No. 30458 drive ring bushings. After installing these parts, grease them.

The Humming Noise.

From Reader, Rhode Island.—Perhaps the hum in the gearing noted by Frank Revellette, Jr., No. 1664, may be due to the mesh of the pinion and crown gear. The correcting of an improper mesh requires



Digitized by Google

experience and is best undertaken by the service station. Humming gears, as experienced by Mr. Revellette, are not uncommon. The sound being attributed to the gearset may be due to the drive shaft housing acting as a transmitter of the noise.

Speed on City Streets.

From N. G. Near, New York.—When you are running at top speed, how much distance do you need in which to safely stop? By a safe stop, I mean a stop that will not in any way hurt the car's brakes, tires or unduly strain any part. I ask this question because it is evident by a study of this diagram that there is a certain maximum speed at which you can safely drive through streets.

I have chosen a street that is 100 feet wide between buildings. Cars A and B are running toward the street intersection, both at the same high speed, and are equally distant from C, where they will very

Speed Dangers.

likely collide if they cannot stop before reaching C. The car drivers cannot see each other until they reach points A and B, on account of the building, D, which obstructs the view. They will then see each other along the dotted line, A B, which is the shortest distance possible and is therefore the most dangerous.

It will be noted, by studying the diagram further, that the distance B C is exactly equal to the width of the street, or 100 feet. And no matter where the cars run, if both are running in the middle of the street, this distance will still be 100 feet. The width of the sidewalk therefore makes no difference, the only requirement being that both cars must run strictly in accordancee with the city's road rules.

Therefore, generally, the width of the street is the criterion. You must always be able to stop within that distance. Make it half the width and you will be even safer. The above, of course, ignores pedestrians entirely.

Novel Device to Teach Driving.

A novel device to aid women motorists, and men for that matter in learning to control their cars without the necessity of getting out into the traffic, has been developed by Bishop, McCormick and Bishop, Dodge Brothers dealers in Brooklyn.

All four wheels are jacked up and the pupil takes the driver's seat and is instructed in starting the car, etc. A semaphore with several arms is placed in front of the car. These arms are controlled by the salesman who stands beside nearby. By pulling the proper cord he causes an arm with the phrases "Road Closed," "Steep Hill," "Bad Curve," etc., to be thrown before the car and the pupil is required to do the proper thing in handling the car in this emergency.

The device has proven a great help in instilling confidence in people who wish to learn to drive in a short time and it has been adopted by a number of motor car salesmen in the East.

That Leaking Carburetor.

From C. S. Venable, Kentucky.—In looking over the July, 1915, number, page 55, question No. 1644, Joseph Pernot, Wisconsin, asks the cause of his Kingston carburetor on a Ford car leaking. I had the same trouble myself some time ago, and tried exactly the same remedies, in exactly the same order as he did, with no result. The trouble lies in the valve that admits the gasoline to the carburetor. Unscrew the pack nut that connects the gasoline pipe line and the bottom nut on the bottom of the carburetor, which will admit of the bowl being taken off. Then carefully introduce some fine valve grinding paste around this valve seat and grind the valve exactly as you would an engine valve, using a small screwdriver, being very careful when through grinding to wash out all the grinding paste with gasoline from a squirt can before replacing the bowl. The trouble comes from this valve being slightly worn on the side, preventing it from closing the hole completely when the float is at its highest point. Perhaps he has found the trouble by now. Anyway, I know it worried me quite a bit, not because of the loss of gasoline, but for fear of fire in leaving the car standing on the street. Mine acted exactly as he describes his, and this seemed so near an absolute parallel case that my sympathy went out to him. Don't be afraid to grind it good, as the first grinding I gave mine was not enough, necessitating a repetition of the process. Use only fine paste, but that needle is "some hard" material.

Turning Garages.

Some one suggests that the person who built a private garage on a turntable so that he can always drive his car head in and head out, would have saved some expense if it had provided a cheap turntable in the garage itself.

The advantage of the turning garage rather than the inside turntable is that automobiles are far longer than they are wide. With an inside turntable, the garage must be as long one way as another, and this of course adds something to the bill for construction. Yet this plan will hardly offset the additional convenience of the turntable in the garage, which does not require a door at each end.

NEW YORK, OCTOBER, 1915.

Missing Numbers—Our Readers are requested to remember that it always gives us pleasure to re-send numbers which have gone astray in the mails.

The Automobile Dealer and Repairer in Australia and New Zealand.

Mr. R. Hill, Matlock House, Devonport, Auckland, New Zealand, is our accredited representative in Australia and New Zealand for obtaining new subscriptions.

WARNING!

Our readers are cautioned to pay no money to a party by the name of A. H. Love. He has been soliciting subscriptions for the Automobile Dealer and Repairer in California and the far West. He was formerly a representative of ours but is no longer in our employ. Parties paying money to Love will do so at their own risk.

PRICES AND PROFITS.

No one should imagine that because some of the automobile stocks have had a recent unprecedented rise in price in the open market following reports of abnormal earnings, that the business offers attractions for investors, either in new enterprises or in those already existing.

Even if a better car at the same price or as good a car at a less price could be produced, the chances of the success of a new enterprise would be extremely doubtful without almost unlimited capital. To occupy a field not already occupied, producing something for which there is a demand, may not be difficult; but to drive others from a field already well occupied is a venture fraught with uncertainties and dangers.

The automobile of to-day is pretty well standardized. The novel or irregular form of construction has pretty well weeded itself out automatically. What variations exist in automobile construction are largely a matter of taste, and there is no complete consensus of opinion as to whether one form or matter of detail is better than another or not. The advantage of choice largely consists in price, material, and the way it is put together. And in this the difference in value as compared to price is less than is usually imagined.

The abnormal profits made the past year by a few manufacturers have been largely due to their export trade on account of the European war or to the advantage of enormous production, or to both.

The price of standard cars may be somewhat reduced within the next year or two, but not enough to warrant any one holding off from purchasing now provided he needs a car.

HOW MORE CARS MAY BE SOLD.

Do automobile manufacturers want to sell from 10,000 to 15,000 more cars right here in New York City and the same proportion according to size in many other large cities?

It can be done by the requisite effort. The reason why many do not purchase cars who want them and who can afford to buy them in this and probably many other large cities, is owing to the garage expense. They can afford the purchase cost and they can afford the cost of running. When an automobile is used but once or twice a week, the running expense is not prohibitive to a man with a comparatively small income. Salaried men or wage workers who have incomes of from $1,200 to $3,000 a year can afford to own pleasure cars, and living in a large city they need them more than if they lived in the country.

A trip into the county or suburbs of the city once or twice a week would be more beneficial to body and mind than any other pleasure that could be enjoyed at anywhere near a similar expense. But the garage cost makes this at present prohibitive.

Possibly a lower cost should not be expected as long as the garage-keeper does the car washing and attends to the other little care that it may need, for this necessitates the employment of more or less help who may sometimes be overworked and at others have absolutely nothing to do. But they must be paid, whether they work or not, and their wages are a serious addition to the cost of garage-keeping.

On the other hand, many who would like to own automobiles and who can afford the purchase price, would be willing to wash and care for them and thus save this heavy expense. In fact, the physical exercise of washing a car and overlooking it to keep it in good running condition would be a positive advantage to many. Quite likely, too, when the owner and driver washes and cares for his own car, the washing and the care may require less work than when he is obliged to pay someone else for the work. He will avoid the mud and water in the road and ride more judiciously over bad places when he knows he himself must keep the car in presentable appearance and in good running order. Recently, while taking a Sunday walk, we ran across a man in an out-of-the-way place in the city suburbs who had his runabout pretty well dismantled by the roadside. He said he took his car out there frequently, believing this was the best place and the best way to care for it himself, and that the expense and time was thus comparatively small.

There should be, and there can be, in this city,

Digitized by Google

garages where the owner washes his car and otherwise cares for it, thus paying for storage only, no help being needed by the garage owner save possibly a watchman at night. The car owner or driver might have simply a stall for his car, and when it requires cleaning, let him roll it over to one of the washing stands provided for this purpose, and do the work himself. Three or four such washing places might be needed, in order that there would be no unnecessary delay.

A garage of this sort to store 100 cars might be built for from $15,000 to $20,000, even in this city of high building and land cost, and the revenue of $5 a month for storage charge would provide ample income on the investment. A return of $6,000 a year would provide for the entire expense of ground rent, taxes and whatever help might be needed.

It is true that many car owners would under no condition wash or care for their own cars, but the number who would do so, and who could afford to own cars if such provisions were at hand, would be twice as great as the class first named.

The attention of automobile manufacturers is directed to this field for the disposal of thousands of pleasure cars. Let them inaugurate a concerted movement to supply this garage need in this and other cities.

It is the garage expense in large cities that acts as a deterrent to thousands who can afford to purchase automobiles and who would gladly purchase them if a way be provided whereby they might have them stored at a reasonable cost.

NO ROOM FOR THEM.

That most worthy association, the American Society of Mechanical Engineers, has recently held a discussion of soldiers made cripples by the European war. In a notice sent out by the society it was stated:

"There are 2.000,000 men living in Europe, who have suffered the loss of limbs, faculties or both as a result of injury in the great war. The study of adapting these crippled men to machines for manufacturing operations, or of redesigning the machines to fit the men, is a problem which the mechanical engineer will have to solve in the near future, not only in Europe, but here in the United States where a great number of the helpless will migrate."

Much as these mutilated men may deserve sympathy, to allow "a great number of the helpless to migrate" here would be an injustice to our own people, and if favors cannot be bestowed upon the few without doing an injury to the many, they should be invariably withheld. For the countries for whose flag they fought to care for them is simple justice; for this country to care for them is simple charity. And justice has a far higher claim than charity.

If any benevolently inclined citizens of this country feel disposed to send funds abroad to contribute to their support, by all means, let them do so. It will redound to their credit. But for the countries which are responsible for the two millions of cripples to send them to this country, or even to allow them to come here, would be heartless and contemptible.

But from an economic point of view there is a far more important reason why these unfortunate cripples must not be dumped into this country. When the war has ended and things in the industrial world settle into their normal condition, there will be no more work than our own cripples and non-cripples need. Even under present conditions of enormous output for foreign countries, there is no special scarcity of labor here. In fact, there never can be, when there is such a plethora of labor that the uneconomic and purely benevolent idea of a "minimum wage law" has obtained such headway.

THE MATTER OF WEIGHT.

That the less the weight of an automobile the less the cost of fuel, oil and tires, goes without saying. But weight reduction must be made, if at all, with a good deal of discretion. Many of our readers will remember in the good old bicycle days, the craze for light weight was such that finally the wheel began to have such a writhing and distortion, and so much vibration, that its propulsion was harder than that of a heavier and more rigid wheel.

Among the parts of an automobile that will bear reduction in weight to the limit of needed strength, are tires, pistons, piston cranks and the body or tonneau. The lighter these can be made the easier the car will propel. But any reduced weight of the frame, the axles or the wheels, that adds the slightest to their distortion or vibration, is a decided disadvantage. Not only will this increase the power needed for propulsion, but it will make the car more uncomfortable to the occupants and hasten its final destruction.

It will be found that in different cars the comparative weights of each bear less relation to the amount of fuel consumed in a given distance of travel than may be imagined. In the case of tires, the relative wear as compared to the weights of different cars is practically the same, no matter what the difference in design and construction may be. But here the difference in wear will not be in exact proportion to the difference in weight. That is to say, a car weighing 2,000 pounds will not wear out tires twice as fast as one weighing 1,000 pounds.

BUYING A CAR.

It must not be assumed that the look of a car or the look of the house organ of the company that manufactures the car are much of a criterion of the car's value. Paint and varnish can be made to cover a multitude of sins of omission and commission, and a well printed pamphlet is often due to the talent of a printer plus a satisfactory emolument in payment for the work rather than to ability in automobile designing or construction.

Paint and varnish as well as good printing are useful in themselves; the two first add to the appearance of a car, and the second to the appearance of whatever is printed. But they have no other effect whatever upon an automobile.

In an expenditure of from $400 to $4,000 a man should first know all about the material and construction of his intended purchase; he should insist upon getting a demonstration of the proposed car, and if he is not familiar with the riding qualities of other automobiles of about the same class or price, he should share that demonstration with some one who is familiar with them, and in whom he has confidence; and he should get in touch with other owners of the same model of car if possible.

Of course, the reputation of the manufacturer is

Digitized by Google

important, but it must be remembered that this does not come like a mushroom in a night, so to speak; it is something of slow growth, and even the most meritorious may be handicapped by the lack of it. Nothing should be condemned simply because it is new, but anything new demands a closer investigation and a more thorough test than if it were already established.

STREET DANGERS.

Automobile accidents continue in New York City with alarming frequency. During the past month scores of children have been killed or maimed by them, and this of course is due to allowing the youngsters to play in the streets. When any one makes a protest against the use of the streets as playgrounds, the reply of the fond parents is usually to the effect that they must "play somewhere," and that in view of the rule, either written or unwritten, that they must not loiter on the stoops of the tenements or apartments where they reside, and that there is no room for them in the parks even if it were practicable to send them there, the question arises, "where can they play?"

Well, for the children's sake and for the parents' sake, inconvenient as it may be, more families with young children should live in the suburbs. It is often inconvenient, it is true, but the lives, to say nothing of the health, of young children, is worth inconvenience. If not, then they should not be brought into the world. Nor is this all. In altogether too many cases, parental discipline as to carelessness in using the streets as playgrounds, seems to be "more honored in the breach than in the observance."

Nothing can be more exasperating to automobile drivers than the gross negligence or the bumptious indifference of some of these youngsters to all warnings of danger. The fact is, such children have been spoiled by "sparing the rod," and it is useless to disguise it.

But automobile drivers have another just grievance, and although it is less exasperating, it is none the less real. When a pedestrian is using or crossing the street, and sees a car approaching, instead of continuing to walk if he were walking or to stop if he were stopping—without change of movement, he often dodges one way or another, until it confuses the driver of the automobile so that he scarcely knows which way to turn.

Pedestrians should not forget that the driver of an automobile constantly has his eyes fixed ahead, and no one or thing can be before him without his knowledge. It is only when a pedestrian or some vehicle suddenly appears directly before and quite near his car that he is unable to avoid a collision, and even in such case he can usually avoid it if he is driving judiciously.

The remedy for so many automobile accidents in city streets is not a fixed slow speed law; a safe speed law applicable to all places and at all times would vary from three to forty miles an hour. The most practicable remedy would be to leave the matter of a dangerous speed to the police force, and as policemen have not the power of ubiquity or of being at all places at all times, possibly it might be well to include the members of the street cleaning department as speed officers. It is true that the street cleaners may not in all cases possess ripe judgment, but almost anything is better than leaving the streets in their present dangerous condition, and discreet drivers would not be likely to often suffer from such surveillance.

The main consideration is that the streets be fairly safe, and that whoever jeopardizes this safety, whether it be old or young, pedestrian or vehicle driver, should be punished without mercy. The streets are for the convenience of vehicles and not for loiterers and much less for playgrounds. Pedestrians have the side and cross-walks for their use, and as for playgrounds, no matter how much they may be needed, the streets must not be given over to them.

NOT FOR CITY DRIVING.

Many imagine that a horse is displaced for every automobile that is sold. Nothing could be wider of the fact. Quite likely that more than fifty per cent. of the car owners of the country did not own a horse and never would own one.

This situation is specially apparent in the large cities. At the upper part of this city there is a large field where the ball games of the two leagues are played. With approximately the same number attending a few years ago there might be from 25 to 50 horse-drawn vehicles standing at the entrance, where to-day there are four or five times as many automobiles.

It is a fact that the automobile has increased enormously the pleasure riding in the large cities. The horse is well adapted to horseback and park driving but when it comes to taking a trip from the central parts of large cities to its suburbs or far into the adjoining country, he is unfit for it.

RISKY PUBLICITY.

Requests are frequently received at this office to publish notices of suits having been filed or begun in relation to some alleged patent infringement. Of course, any one has a right to enter such a suit, no matter whether the case be a substantial or a flimsy one. But no discreet periodical will publish the fact that such a suit has been filed or begun, for the reason that if it should not be successful, or be withdrawn, the defendant can sue the periodical for damages and get from it all the damage that such publishing has caused him.

It is plainly an injury to any business when the public, or its customers, are given an idea that it is being done in an unlawful manner. Our invariable refusal to make mention of suits of this sort can be accounted for by the facts as stated.

Concrete Roads.

California has built 800 miles of concrete roads during the last three years, and New York State ranks second. They are also being laid extensively in Michigan, Illinois, Wisconsin and Iowa. The cost per mile for a 15-foot road is about $7,750.

A loose terminal on a plug can cause intermittent firing, and a not properly tightened plug center can do the same, but, what is worse, can lead to a serious backfire, with the chance of a broken wrist.

LESSONS FOR DRIVERS.

Carelessness and Ignorance Responsible for Most Accidents.

Crossing Partially Obscured.—At Grenada, Oregon, a family of five were killed at a railway crossing which is partially obscured by a house and a line of trees. The driver could not get a view of the track until right upon it. The car stalled as soon as it struck the track and the express train crashed into it. Several serious accidents have been narrowly averted at this point in the past.

Snake Causes Accident.—Near Eagle Grove, Ia., a bad accident occurred, when some malicious youngsters threw a snake at a car filled with young lady passengers. It wrapped itself around the driver's neck and when he grabbed for it with both hands the car turned out of the road and collided with a tree. One of the ladies was thrown through the windshield sustaining a severe cut in the back and face.

Slid Down Hill Onto the Track.—One man was killed and two others injured near Racine, Wis., when the car in which they were riding slid down a mud and gravel hill on to the car tracks. The driver applied the brakes as he heard the train coming but they would not hold and the car was struck with results as stated.

Talking With Companion.—A young lady in Chico, Cal., received painful injuries when she was jammed against an iron fence in front of the school grounds. It is said that the lady driving the car was talking with her companion and did not notice she was approaching the entrance to the school grounds. She turned the wheel quickly, but as the gate was closed she crashed against the fence, breaking it and striking the young woman.

Loses Control of Car.—Three boys from 15 to 16 years, near Clinton, Wis., started on a midnight ride in a big touring car. A long hill proved an incentive to the boys to speed and the car went down the hill at a fast rate. The boy that was driving lost control of the steering wheel, the front wheel struck a rough, sandy road and the car turned over the embankment. One of the boys was found underneath the machine dead and the others escaped with injuries.

Made a Quick Turn.—A man, two women and a baby were injured near Youngstown, Ohio. On coming to a turn in the road the driver saw a car ahead of him, going in the same direction. In making a quick turn to avoid a collision with the car ahead, the automobile was overturned and the occupants thrown out. The other car started ahead without offering any assistance.

In an Attempt to Reach a Hat.—One man was instantly killed, his wife severely injured and two other occupants of the car hurt near Council Bluffs, Ia., when the driver in attempting to rescue a hat of one of the passengers lost control of the car and the occupants were hurled into the ditch and pinned beneath it. The driver was caught with his face buried in the ground and suffocated.

Killed by a Locomotive.—Three women and a man were almost instantly killed near Montague, Cal. At the point where the accident occurred there is an abrupt curve, and the approach of railway trains is not noticeable. The driver undertook to stop his car and reverse when he saw the train almost upon him and thus became stalled directly in the path of the train.

Struck by a Second Trolley Car.—At Richfield Springs, N. Y., a young man was instantly killed and a young woman seriously injured when the car in which they were riding was struck by the second passing trolley car. It is stated that the crossing was obscured by brush and the approaching car could not be seen until it was too late and the driver assumed, as one car had just gone by, that the track was clear.

A Bad Spot in the Road.—Near Salem, Ohio, a woman received injuries in an accident from which she died soon after, when the car in which she was riding struck a deep depression in the road and was ditched. It is said that the condition of the road at this point was called to the attention of the trustee before the accident but he neglected to have it repaired.

Tried to Pass on Narrow Road.—Near Mayfield, S. D., a woman and her son were killed. The road was steep and narrow and the driver attempted to pass a car going in the same direction and drove too close to the edge of a grade. The car toppled over, made a complete somersault and stopped right side up. The woman's head was crushed and the young man's back broken.

In Explaining the Operation of the Car.—At a bad turn in the road near Sacramento, Cal., a woman was thrown 20 feet from a car and killed almost instantly and a man died soon after, when struck by a train at the crossing. It is stated that the driver had the party out for a demonstrating ride and was explaining the mysteries of the car to prespective buyers.

Failed to Carry Sufficient Water Supply.—Failure to think of evaporation in an automobile radiator brought death to one man and tortures to two others in the Imperial Valley, Cal. The car stopped in the sand, the radiator was empty and they had no water. One of the party made his way to Mineral Springs and formed a rescue party. When he returned one of his companions was dead and the other unconscious.

Jumped from Moving Car.—At Enid, Cal., a young boy was killed when he and two others were riding to school. The driver slowed down as they neared the school and the boy jumped. His foot slipped and he fell beneath the car and a wheel passed over his neck. He died on the way to the hospital.

Driver Falls Asleep.—Four men were injured, two seriously, when the driver of the car in which they were riding fell asleep and the machine struck a concrete bridge and rolled over into the ditch. The car was completely demolished.

Inspect Your Tool Box.

An inspection of most motor car tool boxes, for instance, will bring to light a collection which usually includes several broken parts of sparking plugs, nuts and bolts that have lost their threads, and spanners that ceased their useful life years ago, etc., and the motorist considers that, in carrying this heterogeneous assortment, he is well provided as regards the question of "spares." The usual result of carrying this unnecessary impediment is that when anything is wanted quickly it is difficult to find. It would, therefore, be a good idea were motorists to devote a wet afternoon to going carefully over the tool box, and throwing out all the obsolete litter.

THE STARTING SYSTEMS.

And Their Possible Ultimate Effect Upon the Use of the Magneto for Ignition.

From J. T. C., Motor Magazine, London.—The present condition of the motor trade, owing to the difficulty of obtaining British-made cars, has brought American-made cars into greater prominence than ever before. It has also casued much attention to be given to the American practice of combined electric starting, ignition and lighting. This elimination of the magneto has caused many to question the wisdom of the British firms that have undertaken its manufacture. If the magneto is really doomed it means a great financial loss to those concerned. The utility of self-starting and electric lighting are accepted facts. The question is centered on the wisdom of combining the ignition with the electric system and dispensing with the magneto.

One of the most important points, especially at the present time, when few skilled driver-mechanics are obtainable for private service, is the simplification of all parts of the car and the elimination of all unnecessary complications. The owner-driver must be especially considered, and should himself give particular consideration when purchasing a new car to complications that would need skilled attention. To examine one American system, characteristic of most others, is sufficient for our present purpose. This particular system has a combined starting motor and lighting dynamo. It is necessary in this case to have a double-wound armature, which, although it simplifies the machine in appearance, actually complicates matters in the case of a breakdown. In the event of either winding failing it is almost certain to affect the other. The lighting dynamo actually generates the current for the high-tension system, and is called the magneto, when charging the accumulators. In the case of failure of this motor-generator one has to fall back on the low-tension system. The low-tension circuit depends on a set of six dry cells to supply electric current through a relay and an induction coil. In the case of the dynamo failing to charge the accumulators, which is somewhat frequent, it is necessary to fall back on the dry cells. If the latter have been in the car some time their condition is uncertain.

In addition to and combined with the foregoing are a cut-out relay, voltage regulator, ignition relay, magneto induction coil, battery induction coil, magneto timer and distributor, battery timer and distributor, a junction box containing the magneto resistance, a magnetic clutch, ammeter, voltmeter and a three-way switch. This formidable array of delicate instruments all need attention at some time or other. Their proper adjustment is the work of a skilled electrician. Not one garage in a hundred would care to undertake tuning up such a system. Compare the foregoing with a high-tension magneto that has only one adjustment, and the question of simplification is answered.

The Question of Breakdown.

It is most important that any car owner should have freedom from the risk of breaking down on the road. In the case of such a misfortune, the ease of quickly finding the trouble is of great advantage. The reliability of the magneto is well known to all having any connection with motoring. It is not an exaggeration to say that there are many thousands of car owners with years of experience who have never yet had ignition trouble that caused a complete breakdown. In any case the magneto is simplicity itself, and the trouble is easily found should it occur. There are only five wires on a four-cylinder engine that can cause a short circuit, and all are accessible. On the combined system being discussed there are 53 wires, each of which may cause trouble and affect one or other of the ignition systems. The majority are more or less exposed to the oil and dirt which accumulate around most engines.

As already mentioned the armature has two windings. Being a low-tension direct current machine it necessarily has two commutators, one for the dynamo and one for the starting motor winding. Each winding is made up of a large number of coils. The two ends of each coil are led out and connected to separate segments in the commutator. The segments of the latter must be insulated from each other, and, of course, from the armature shaft. Taking the machine as a whole the number of insulated parts must be well over a hundred. Each insulated part is a likely cause for future trouble that will affect the high-tension circuit, making it necessary to fall back on the doubtful dry cells. The insulated parts of the many instruments named, which are included in the ignitions, are too numerous to detail, not forgetting the terminals of the 53 wires.

The insulated parts of the ordinary high-tension magneto are negligible in comparison. At the same time it is admitted that the machine itself generates at a very much greater voltage, but experience extending over a number of years has eliminated any points of weakness and added greatly to its reliability.

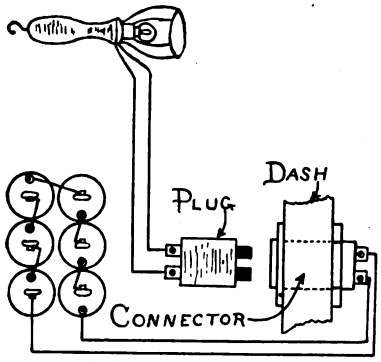
The Question of Cost.

The comparative cost of installation is in favor of the magneto. A new high-tension magneto of the best type costs about $50. A dual ignition set costs 50 per cent. more. An electric light set, including dynamo, battery and lamps, cannot be installed for less than about $150. A combined lighting and starting set costs more. It is somewhat difficult to arrive at the possible cost of a set combining starting, ignition and lighting.

When buying a cheap car which includes starting, ignition and lighting, it is well first to deduct the possible cost of the electric installation; then consider if the difference is sufficient to guarantee the sound mechanical construction of the chassis and good bodywork.

The convenience of self-starting is certainly very pleasing, but it is a dispensable luxury. Electric lighting has great advantages over oil lamps, and is an improvement on acetylene gas as regards cleanliness and convenience. Its only fault, up to the present, is the somewhat doubtful reliability of the dynamo. As a generator of electric current it is far from the perfection attained by the high-tension magneto. It is for the latter reason inadvisable to rely upon the lighting dynamo to generate current directly, or indirectly, through accumulators for the high-tension ignition system. If the dynamo is reliable why are special directions given in the instruction books for charging the accumulator from an outside source, and why is an alternative ignition system provided? In the case of the high-tension

Digitized by Google



magneto reliability is so sure that very few cars carry a dual ignition set. When the latter is provided it is not a "stand-by," but a convenience for easier starting.

If the matter is given careful consideration only one conclusion can be arrived at—that the magneto will continue to hold its own. Especially so in the case of owner-drivers where simplicity and reliability are the controlling considerations.

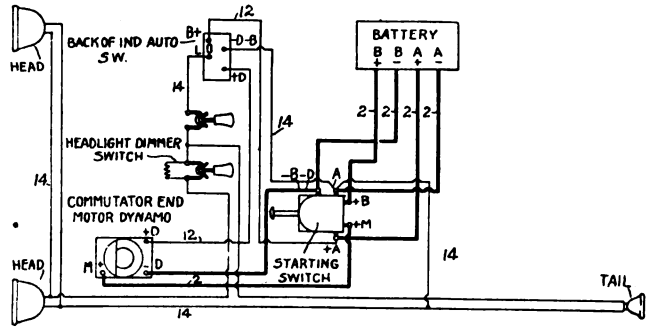
Installing Handy Trouble Lamp.

Owners of cars not equipped with electric lighting can install a convenient trouble or inspection lamp at a slight cost. The usual method consists of attaching the wires of the lamp to the battery or dry cells, an arrangement requiring the removal and replacement of the battery terminals, an operation taking more or less time.

The installation shown in the accompanying illustration eliminates the work and with it the lamp may be connected very quickly and easily. The material required is a dash plug and connector and these come in two forms, for metal and wooden

Trouble lamp permitting of easy and rapid service and permanent connection with battery.

dashes. That shown is a wood member and one section is installed by boring a hole in the dash and fitting the connector. The terminal ends of the connector are placed on the motor side of the dash and to these are led the two wires from the battery or dry cells. The plug is attached to the wires leading from the trouble lamp. The convenience of the arrangement is obvious. When use of the lamp is desired the plug is inserted in the connector which closes the circuit, supplying current to the lamp. The connector can be permanently wired to the battery or cells employed for ignition or other purposes without interfering with the operation of the motor or other electrical units. As the connector is flush with the dash it does not detract from the appearance of the latter. The installation can be made in less than 30 minutes. The material can be obtained at any supply house, and as above stated is inexpensive.



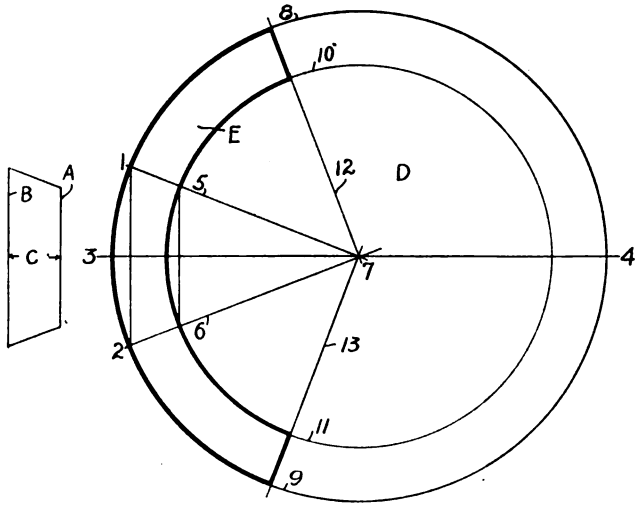
No Horse-Drawn Vehicle.

One of our correspondents writes that he recently spent Sunday in Cleveland, Ohio, and the room he occupied in one of the hotels overlooked the famous Euclid Avenue. He said that for two hours he watched the procession of automobiles go back and forth and didn't, in all that time, see one horse-drawn vehicle.

This little incident illustrates to what an extent the automobile has supplanted the horse in one of the principal cities of the country.

Wire Testing with a Bell.

A method employed in wire testing is shown in the illustration. With the use of an electric bell and a dry cell battery, it is an easy matter to find if the wire is broken inside of the insulation, from the



Battery Test.

lamps to the battery. Connect wire A to lamp from one side of the bell, and wire B to the post of the dry cell. Then from the dry cell to the wire of the storage battery, as shown at C. If the bell does not ring the wire is broken and the cause has been discovered.

A New Leather for the Clutch.

Owing to the shape of the surface of a cone clutch it is not an easy task to cut a new leather to fit the cone properly. In the first instance take off the old worn leather surface and rivets and be sure to clean out the rivet holes thoroughly. Now that this is accomplished, measure the cone, first taking the diameters of the small end, A, and large end, B, then find the width, C. D represents the projection of the cone in a flat plain. Draw the line 1 and 2, then draw the center line 3 and 4, at right angles to 1 and 2. Now prolong the two tapered lines, 1 to 5, 2 and 6, until they meet the center line as at 7. The point 7 represents the apex of the cone, if it were completed, and gives the correct protection of the development of that portion of the conical surface. With 7 and 1, 7 and 5 as radii, draw the two circles 8, 9, 10, 11. Also draw radial lines 12 and 13 to pass through 7. The figure in solid lines, E, can then be cut out of

For Fitting the Leather.

the paper used for the pattern and placed on the leather. Now use the shears and cut close to the edge of the pattern, E, and the proper cover has been made. Before putting it on the cone soak the leather good in oil. In putting it on the cone, rivet the one end first, next the leather is drawn down past the

Digitized by Google

next rivet holes, which are then driven into place. This is continued until the other end of the leather is reached. Before using the clutch let the leather dry gradually and this will give a tight fit.

Watch your compression. If there is a leak by the piston, it will be shown by a gradual yielding to pressure when turning the engine over by hand. Look after it at once. Rings that fit poorly or are stuck in their grooves, leaky valves, and leaky joints are the principal causes of compression losses. Soapy water or oil will locate an outside leak.

OUTFIT FOR REPAIR WORK.

Some of the Tools and Machines Needed and What They Will Do.

From "Automobile Repairing Made Easy," by Victor W. Page. Published by The Norman W. Henley Publishing Co., New York.

(Copyright, 1915, by The Norman W. Henley Publishing Co., New York.)

There are so many small items of equipment entering into the outfit necessary to carry on repair work economically and efficiently and so many supplies are needed that it is difficult to distinguish be-

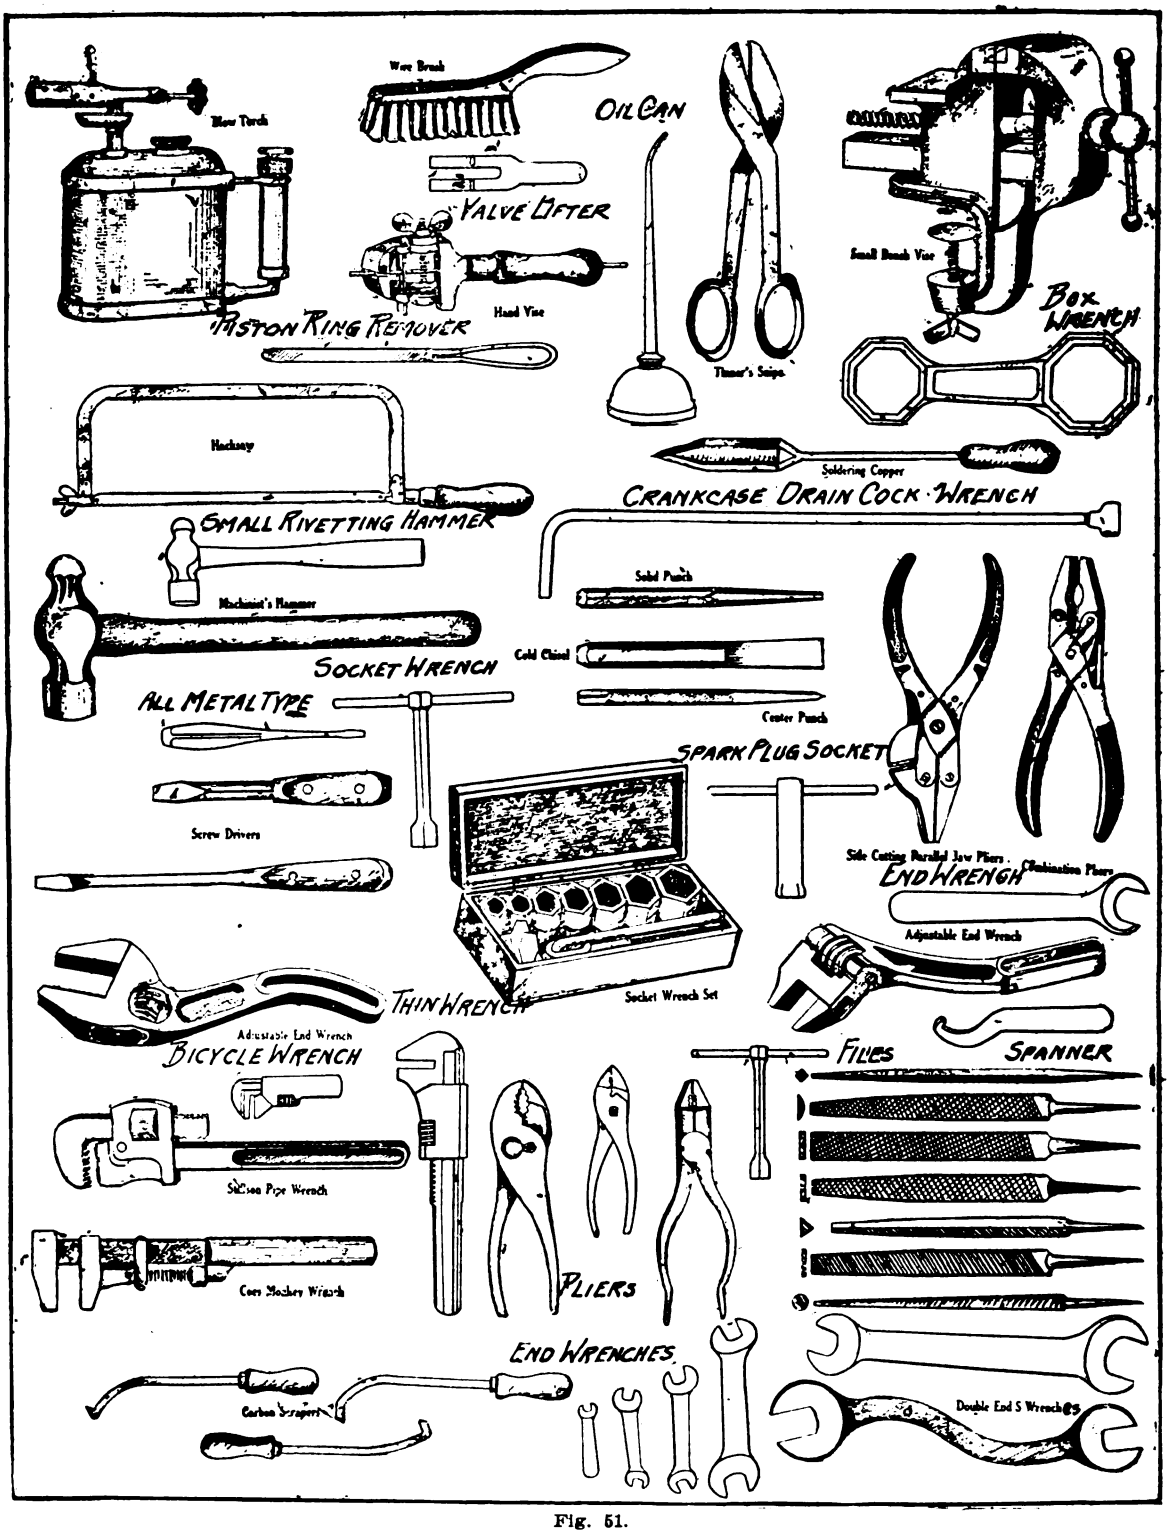


Fig. 51.

Digitized by Google

tween the tools used only on the car and others which serve a general purpose about the garage or repair shop.

Machine tools in themselves are of little value without an adequate supply of smaller tools to be

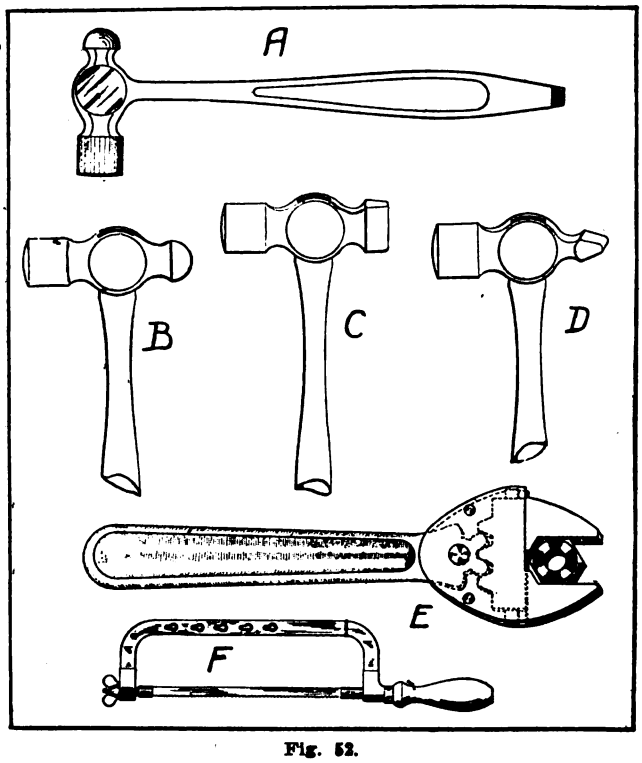

Fig. 52.

used in connection with them. For example, a lathe could not be employed to advantage without a complete set of accessories and cutting tools, while a drilling machine would be valueless if not supplied with proper chucks and drills for making the holes.

A very complete outfit of small tools, some of which are furnished as part of the tool equipment of various cars are shown in group at Fig. 51. This group includes all of the tools necessary to complete a very practical kit and it is not unusual for the floor man who is continually dismantling and erecting cars to possess even a larger assortment than indicated. The small bench vise provided is a useful auxiliary that can be clamped to the running board of the car and should have jaws at least three inches wide and capable of opening four or five inches. It

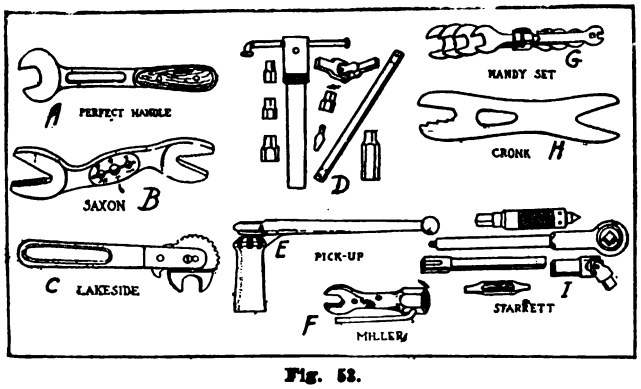

Fig. 53.

is especially useful in that it will save trips to the bench vises and can also be carried as part of the tool equipment by the motorist to advantage, as it has adequate capacity to handle practically any of the small parts that need to be worked on when making repairs. A blow torch, tinner's snips and soldering copper are very useful in sheet metal work and in making any repairs requiring the use of solder. The torch can be used in any operation requiring a source of heat. The large box wrench shown under the vise is used for removing the wheel hub cap and sometimes has one end of the proper size to fit the valve chamber cap. The piston ring removers are easily made from thin strips of sheet metal securely brazed or soldered to a light wire handle. These are used in sets of three for removing and applying piston rings in a manner to be indicated in the next chapter. The uses of the wrenches, screwdrivers, and pliers shown are known to all and the variety outlined should be sufficient for all ordinary work of restoration. The wrench equipment is very complete including a set of open end S-wrenches to fit all standard bolts, a spanner wrench, socket or box wrenches for bolts that are inaccessible with

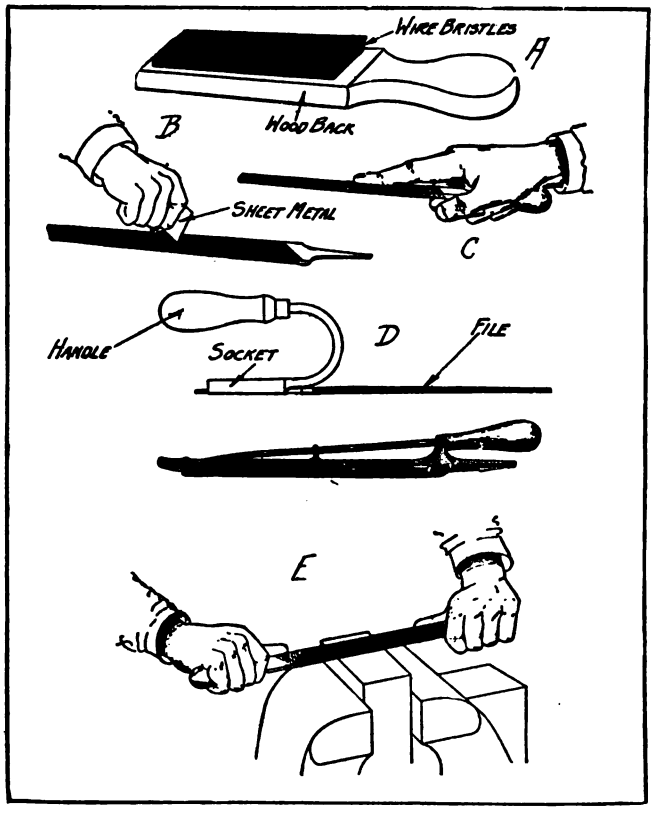

Fig. 54.

the ordinary type, adjustable end wrenches, a thin monkey wrench of medium size, a bicycle wrench for handling small nuts and bolts, a Stillson wrench for pipe and a large adjustable monkey wrench for the stubborn fastenings of large size.

The most popular form of pliers is the combination pattern shown beneath the socket wrench set. This is made of substantial drop forgings having a hinged joint that can be set so that a very wide opening at the jaws is possible. These can be used on round work and for wire cutting as well as for handling flat work.

A very complete set of files, including square, half round, mill, flat bastard, three-cornered and rat tail are also necessary. A hacksaw frame and a number of saws, some with fine teeth for tubing and others with coarser teeth for bar or solid stock will be found almost indispensable. A complete punch

Digitized by Google

and chisel set should be provided. A number of different forms and sizes of chisels are necessary, as one type is not suitable for all classes of work. The adjustable end wrenches can be used in many places where a monkey wrench cannot be fitted and where it will be difficult to use a wrench having a fixed opening. The Stillson pipe wrench is useful in turning studs, round rods, and pipes that cannot be turned by any other means. A complete shop kit must necessarily include various sizes of Stillson and monkey wrenches as no one size can be expected to handle the wide range of work the repairman must cope with. Three sizes of each form of wrench can be used, one, a 6 inch, is as small as is needed while a 12 inch tool will handle almost any piece of pipe or nut used in a motor car. For large work a 16 inch or 18 inch Stillson will be found of value.

Two or three sizes of hammers should be provided, according to individual requirements, these being small riveting, medium and heavyweight machinist's hammers. A very practical tool of this nature for the repair shop is shown at Fig. 52, A, as it can be used as a hammer, screwdriver or tire iron.

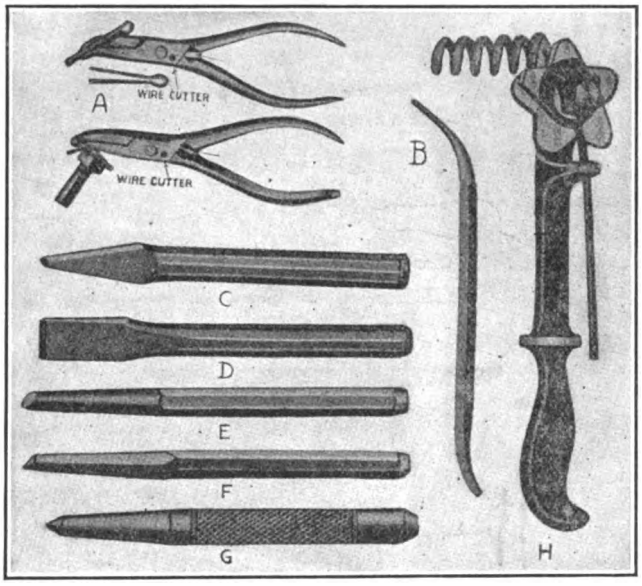

Fig. 55.

It is known as the "Spartan" hammer and is a tool steel drop forging in one piece having the working surfaces properly hardened and tempered while the metal is distributed so as to give a good balance to the head and a comfortable grip to the handle. The hammer head provides a positive and comfortable T-handle when the tool is used as a screwdriver or tire iron. Machinist's hammers are provided with three types of heads, these being of various weights. That at B, is the form most commonly used and is termed the "ball pein" on account of the shape of the portion used for riveting. The straight pein shown at C, is just the same as the cross pein shown at D, except that in the latter the straight portion is at right angles to the hammer handle, while in the former it is parallel to that member.

A self-adjusting monkey wrench which is known as the "speed nut" is shown at Fig. 52, E. The act of pulling on the handle tightens the wrench on the nut by means of a rack which is formed integral with the movable jaw and a portion of a pinion meshing with it at the end of the handle. Pulling on the handle tightens the wrench on the nut and the harder one pulls, the more securely the nut is gripped. The hacksaw frame shown at Fig. 51, is a solid type adapted only to take one length of blade. As hacksaw blades are made in varying

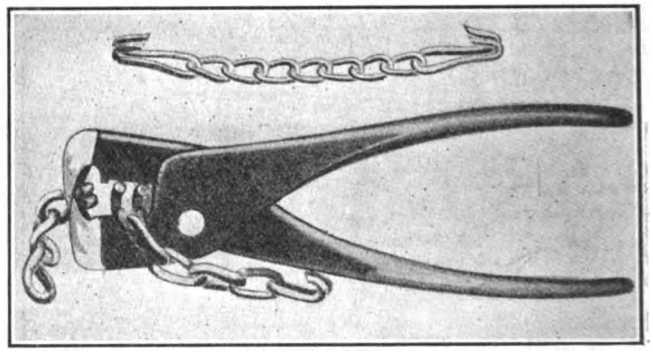

Fig. 56.

lengths it may be possible that a longer one than that frame was made for would be the only thing available. In such a case the adjustable hacksaw frame shown at Fig. 52, F, would permit of using a longer saw blade by merely extending the frame as necessary.

Wrenches have been made in infinite variety and there are a score or more patterns of different types of adjustable socket and off-set wrenches. The various wrench types that differ from the more conventional monkey wrenches or those of the Stillson pattern are shown at Fig. 53. The "perfect handle" is a drop forged open end form provided with a wooden handle similar to that used on a monkey wrench in order to provide a better grip for the hand. The "Saxon" wrench is a double alligator form, so called because the jaws are in the form of a V-groove having one size of the V plain, while the other is serrated in order to secure a tight grip on round objects.

The file brush shown at 54, A, consists of a large number of wire bristles attached to a substantial wood back having a handle of convenient form so the bristles may be drawn through the interstices between the teeth of the file to remove dirt and grease. If the teeth are filled with pieces of soft metal, such as solder or babbitt, it may be necessary to remove this accumulation with a piece of sheet metal as indicated at Fig. 54, B. The method of holding a file for working on plain surfaces when

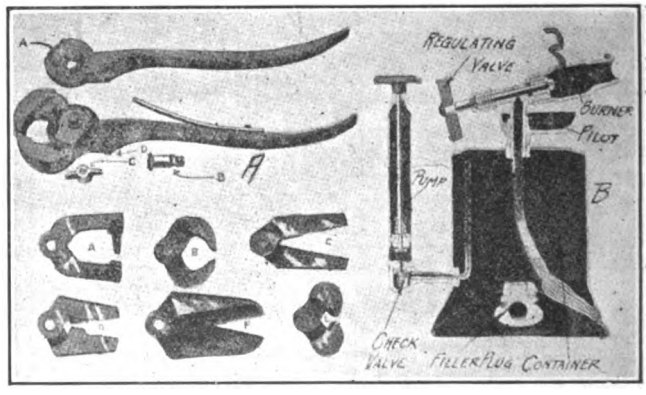

Fig. 57.

it is fitted with the regular form of wooden handle is shown at C, while two types of handles enabling the mechanic to use the flat file on plain surfaces of

Digitized by Google

such size that the handle type indicated at C could not be used on account of interfering with the surface finished are shown at D. The method of using a file when surfaces are finished by draw filing is shown at E. This differs from the usual method of filing and is only used when surfaces are to be polished and very little metal removed.

One of the most widely used of the locking means to prevent nuts or bolts from becoming loose is the simple split pin, sometimes called a "cotter pin."

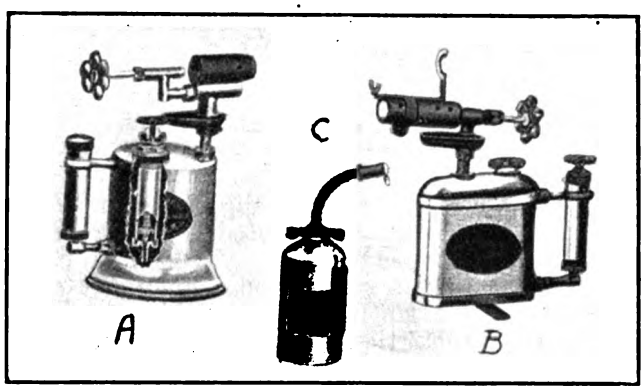

Fig. 58.

These can be handled very easily if the special pliers shown at Fig. 55, A, are used. These have a curved jaw that permits of grasping the pin firmly and to insert it in the hole ready to receive it. It is not easy to insert these split pins by other means because the ends are usually spread out and it is hard to enter the pin in the hole. With the cotter pin pliers the ends may be brought close together and as the plier jaws are small the pin may be easily pushed in place. Another use of this plier also indicated, is to bend over the ends of the split pin in order to prevent it from falling out. To remove these pins a simple curved lever, as shown at Fig. 55, B, is used.

This has one end tapering to a point and is intended to be inserted in the eye of the cotter pin, the purchase offered by the handle permitting of ready removal of the pin after the ends have been closed by the cotter pin pliers.

A complete chisel set suitable for repair shop use is also shown at Fig. 55. The type at C is known as a "cape" chisel and has a narrow cutting point and is intended to chip keyways, remove metal out of corners and for all other work where the broad cutting edge chisel shown at D cannot be used. The form with the wide cutting edge is used in chipping. cutting sheet metal, etc. At E a round nose chisel used in making oil ways is outlined, while a similar tool having a pointed cutting edge and often used for the same purpose is shown at F. The center punch depicted at G is very useful for marking parts either for identification or for drilling. In addition to the chisels shown, a number of solid punches or drifts resembling very much that shown at E, except that the point is blunt should be provided to drive out taper pins, bolts, rivets and other fastenings of this nature. These should be provided in the common sizes.

A complete set of real value would start at ⅛-inch and increase by increments of 1/32-inch up to ½-inch. A simple spring winder is shown at Fig. 55, H, this making it possible for the repairman to wind coil springs, either on the lathe or in the vise. It will handle a number of different sizes of wire and can be set to space the coils as desired.

Anti-skid chains form an important item in the equipment of the car and as they are subject to wear it is desirable to replace the worn cross chains with new ones from time to time, as some of these wear out quicker than others. A special pair of pliers having overlapping ends, as shown at Fig. 56, is intended to assist in removing and applying the cross chains.

A typical gasoline blow torch is shown in section at Fig. 57, B, in order that the internal construction may be readily understood. It consists of a main container of heavy sheet metal to which an air pump is attached at one side to act as a handle. The lower portion of this pump communicates with the interior of the tank by means of a bent pipe which deflects the air to the top of the fuel receptacle. The upper portion of the tank is supplied with a burner having a pipe leading to the bottom. A filling plug is inserted at the bottom of a conical depression which acts as a funnel when the torch is inverted for filling. The function of the air pump is to force air into the tank and displace the liquid fuel, forcing it to the burner where it is vaporized. The burner is of the Bunsen pattern and gives a blue flame. The intensity of the flame is regulated by a needle valve. In order to start the torch it is necessary to

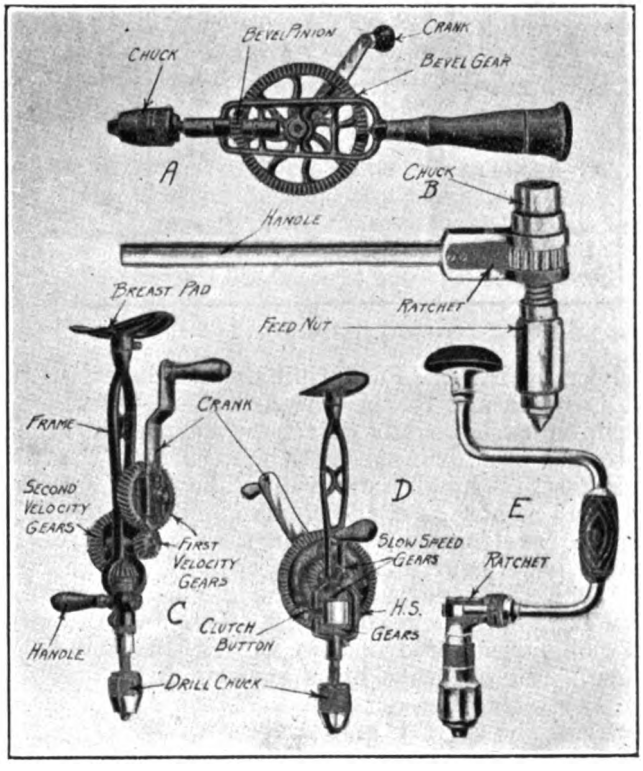

Fig. 59.

fill the pilot cup under burner with gasoline and to ignite same, leaving it burn until the torch burner body is sufficiently heated to vaporize the liquid fuel. Three forms of these blow pipes are shown at Fig. 58. That at A has a pump set into the tank and a more powerful burner that will give a very hot flame for brazing. The torch at B has a flat fuel tank instead of the usual cylindrival form and has the filler opening at the top instead of at the bottom. The flat torch is easier to carry than the round ones because it occupies less space. A very

Digitized by Google

small torch which needs no air pressure is shown at C. Sufficient heat to vaporize the fuel and to start the torch may be obtained by holding a match at the curved portion of the burner. This form does not produce the intense heat that the torches having internal air pressure do, but the flame is of sufficient intensity to heat a soldering iron, or perform any of the work incidental to soldering.

Drilling machines may be of two kinds, hand or

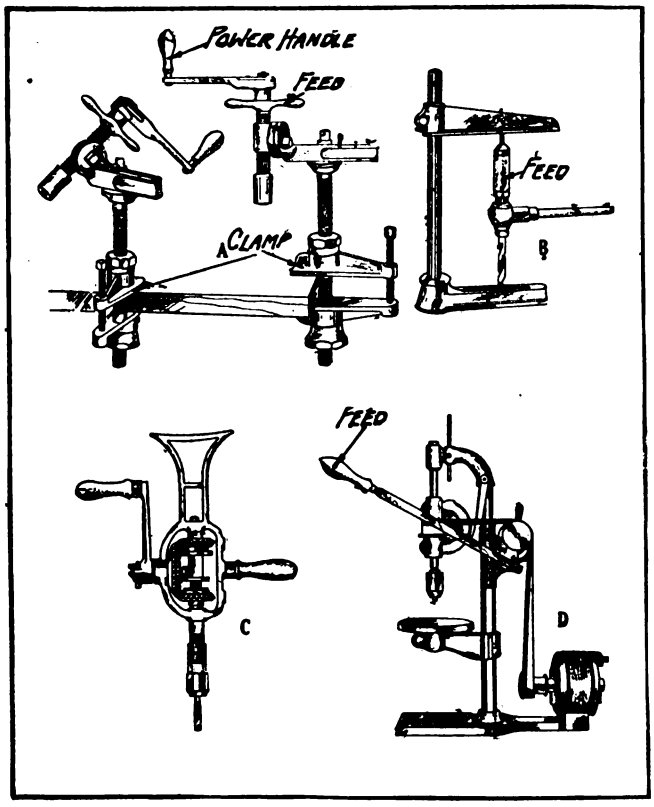

Fig. 60.

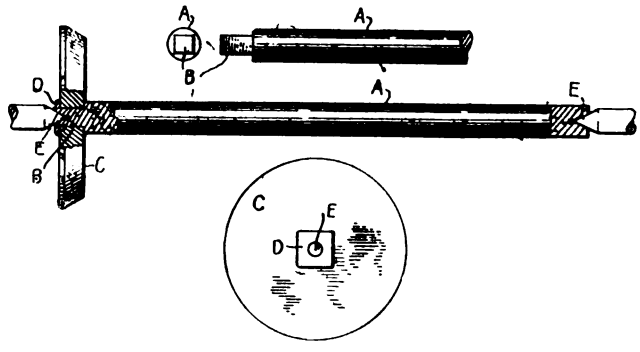
power operated. For drilling small holes in metal it is necessary to run the drill fast, therefore the drill chuck is usually driven by gearing in order to produce high drill speed without turning the handle too fast. A small hand drill is shown at Fig. 59, A. As will be observed, the chuck spindle is driven by a small bevel pinion, which in turn is operated by a large bevel gear turned by a crank. The gear ratio is such that one turn of the handle will turn the chuck five or six revolutions. A drill of this design is not suited for drills any larger than one-quarter inch. For use with drills ranging from one-eighth to three-eighths, or even half-inch the hand drill presses shown at C and D are used.

A handy tool that has many applications is shown at Fig. 60, A. This is mounted on a clamp bracket, has a screw feed, can drill holes at any angle and offers a wide range of adjustment in all directions. These are made in three sizes, one taking any drill up to 5/8 inch, a medium size that can be used up to 1 inch in diameter and a larger model that will bore holes as large as 1¼ inches in diameter. The medium size tool will be found sufficiently large to answer the requirements of any repair shop. The chucks provided will take either square shank or standard taper shank drills. It will be evident that this fitting can be easily clamped to any part of the frame and that large holes may be drilled with ease on account of the leverage provided. A somewhat similar fixture is shown at Fig. 60, B, this being in use with the ratchet drill shown at Fig. 59, D.



KINKS AND THINKS.

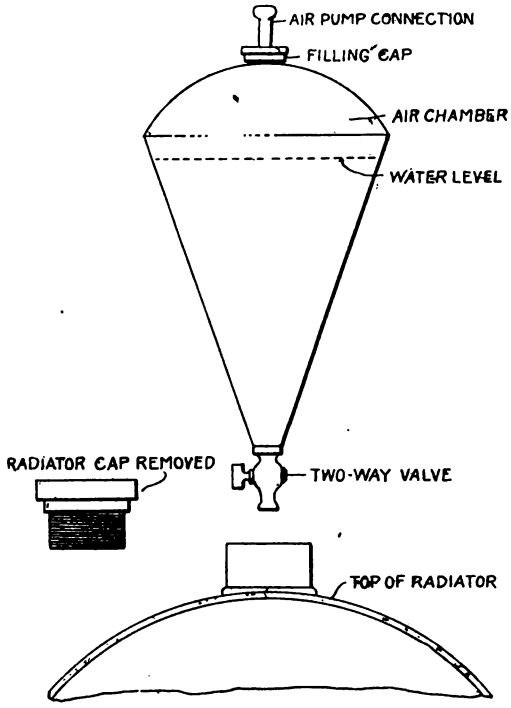
Broken Valves, Radiators, Headlights, Slipping Wheels and Loss of Power.

From N. G. Near, New York.—When a valve stem or valve disc breaks, it is not so difficult as it might seem to make a new valve that will hold its own with the other one-piece valves for a good while. Herewith I show the method that I have successfully used for making two-piece valves where the owner of the car is in a hurry and cannot or will not wait for new standard valves from the factory or storehouse.

Take a mild steel bar, A, slightly oversize, and file a square end on it as indicated at B. Be as careful as possible to make the flatted faces parallel with the axial lines of the rod. Then get a mild steel plate, C, (it can be forged out if necessary), a little thicker than the disc will be when finished, and chip off the corners of the squared piece or in other ways make it as nearly round as you can before placing in the lathe. Cut a square hole in the center of the disc to fit the squared end of the rod A. Don't spend too much time on the job though; just make it a reasonably good fit—a drive fit is preferable for obvious reasons. Then drive together and rivet the end of the rod over to hold the disc solidly in place as at D. Now center the ends carefully, counter sink, as at E, and turn down to the required dimensions. In turning the valve spindle, use a follower rest.

The valve will give excellent service, but, of course, before it gives trouble through loosening or through premature wear it is best to abandon it as soon as a standard one-piece factory made valve is procurable. Whenever I have made a repair of this sort I have always admitted that it is "not as good

When a Valve or Disc Breaks.



as new," and is only temporary. I believe it would be wise for more repairmen to follow such tactics for it stands to reason that a single man with a small set of tools and ordinary materials at his disposal cannot make a better valve than an entire factory which specializes in valves.

I have noticed, at automobile races, that considerable time is consumed at the pits in replenishing the radiator water supply. This is due to the fact that an ordinary funnel is used and the water is allowed to run through the funnel by natural gravity only. Now, the earth's gravity is insufficient in a case of this kind where seconds amount to thous-

Digitized by Google

ands of dollars. I therefore suggest that an arrangement similar to my sketch herewith would save many seconds. Air could be pumped into the funnel over the water while the automobiles are racing, with an air or tire pump. Any pressure could be produced in this way and the water would spurt into the radiator in a "jiffy." Any size of funnel could be made for this usage.

I have seen about a thousand and one ways in which drivers soften the glare of brilliant headlights—paint, soap, tissue paper, talcum powder,

Filling the Radiator.

etc., but I saw the simplest of all the other night when I heard a chauffeur in New York City cursing softly among several co-chauffeurs. His side lamps refused to work and he was compelled to use the headlights which had a ferocious glare. Did he use soap, or library paste? Indeed he didn't. In his handiest pocket he had a bottle of liquid. The shape of the bottle was similar to those that usually contain whisky. He hastily smeared some of this liquid (it had the whisky odor, too) over the headlight fronts, and then, with the dust that he managed to scrape together from the street he manufactured "dark glasses." Then he drank some of the liquid. When he drove off he was singing something about the River Shannon and where it flows.

Wheel slip is bad in two ways: it wears out tires quickly and it eats up engine power. You know about the wear, but do you know how much the gasoline loss amounts to? Have you ever thought of it?

Let us suppose that you are in a mud hole; that the engine and wheels are running at normal speed —about 30 miles per hour—but you are not getting anywhere. The engine is working just as hard as though you were actually running at 30 miles per hour, and perhaps harder. You are using just as much gasoline. The gasoline is all being wasted. The slip, of course, is 100 per cent. Hence, we can make this rule—where the slip is 100 per cent., the full loss is 100 per cent.

Now let us go to a sandy road where the wheel slip is 50 per cent. That is, the wheels are running at a rate that would ordinarily drive you 30 miles per hour, but your car is moving at the rate of 15 miles per hour only. The slip, therefore, is 50 per cent. The amount of fuel used is the same as in the mud hole, but, you are getting somewhere; all of the gasoline is not being wasted. It is logical and correct, therefore, to say that 50 per cent. of the fuel is wasted where the slip is 50 per cent.

From these two examples we can then come to the conclusion that "one per cent. of the fuel is lost for each per cent. of wheel slip." This is a good rule to remember.

Similarly, each per cent. of slip in an automobile friction drive represents one per cent. of loss of power because the pressure of the wheel against the disc is always the same whether there is slip or no slip. And as long as the pressure is the same the engine is bound to do the same amount of work.

It is true that this reasoning is not "absolutely correct" because there are many different possible conditions, to take into consideration. Roughly though, and with good average accuracy, you can safely figure that "each per cent. of slip, no matter what the machine, represents one per cent. loss of power."

"THE CAR AHEAD."

The Pilot Is a Marvel of Convenience, Power and Up-to-Date Construction.

Among the cars where value is given for every dollar of price is the Pilot of Richmond, Ind. The prices are based on actual factory cost, low overhead charges and selling expenses. There is no large watered stock or bond capitalization on which large interest and dividend charges must be paid, and no large salaries. Models now on the market are the four-cylinder Pilot 40—$2,000—with either five-passenger touring or roadster body on the same chassis, the four-cylinder Pilot 50—$2,250—and six-cylinder Pilot 60—$2,500. The beautiful jewel body for either five or seven passengers will be used on the Pilot 50 and Pilot 60. The motor in itself is a marvel of simplicity, lightness, strength and power and represents the latest word in construction.

Every working part of this superior car is easy to reach and it can be handled by a woman for it is practically "fool proof." The Gray & Davis system of starting and lighting is a marvel of simplicity. There are no complicated controls—only a simple switch. The big feature is the fact that it only requires the 6 volt battery which is charged automatically by the dynamo. It starts a car under any conditions and in zero weather which is a feature to remember. It is a specially designed motor which rotates the flywheel—positive in its operation—a pressure on a pedal starts the engine. It will spin a 6 cylinder car for 1½ hours—propel it two miles. The following are the condensed specifications of this unusual car:

Axle (Front)—I-Beam, drop forging. 30 P. C. Steel.

Axle (Rear)—Full floating type, one piece pressed steel housing. Nickel steel gears and shafts.

Bearings—Annular ball bearings in front and rear axle. Special on Pilot 50 and Pilot 60. Silent type annular bearings in transmission. Nickel babbitt bearings in motor.

Body—Fore-door Roadster and Touring Car on

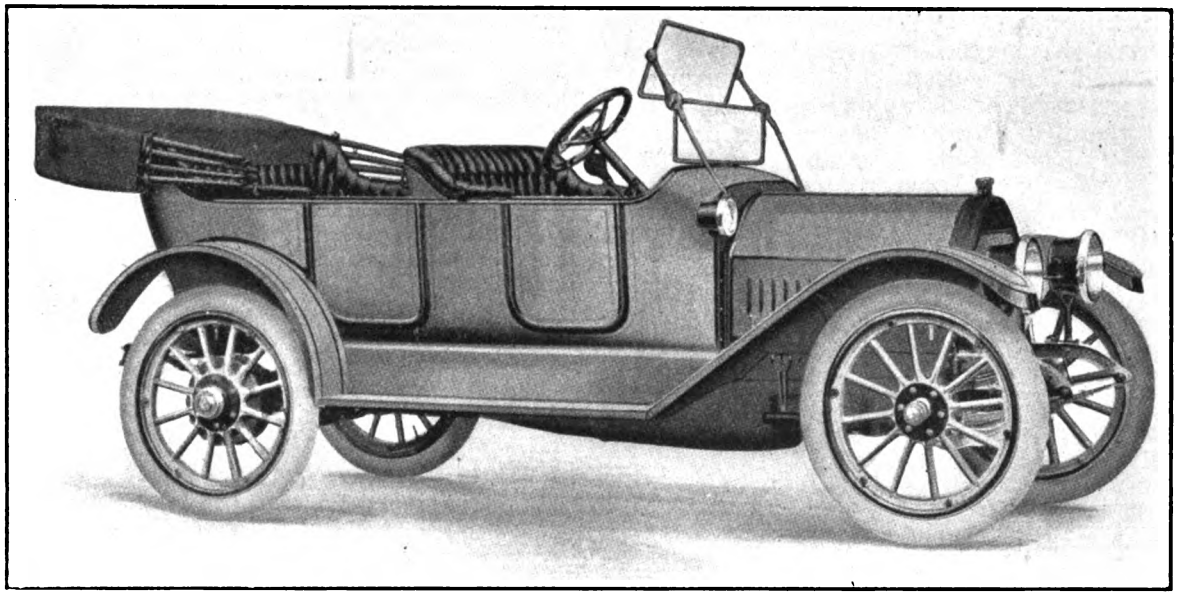
Digitized by Google

Pilot 40. Five and seven passenger body on Pilot 50 and Pilot 60.

Brakes—Internal expanding of large size, both brakes acting on rear wheel drums.

Clutch—Cone, leather faced, auxiliary springs. Engagement very easy. Very efficient.

Cooling—German Silver Radiator. Mayo honeycomb type 4-in. core. Large reservoir surrounding



Springs—Front, semi-elliptic; rear, half-elliptic 52-in. long. Rear spring suspension insures easy riding car.

Steering Gear—Irreversible. Worm and Wedge.

Tank Capacity—20 gallons.

Tires—Pilot 40, 36x4. Pilot 50 and Pilot 60, 37x4½.

Transmission—Selective sliding gears of chrome

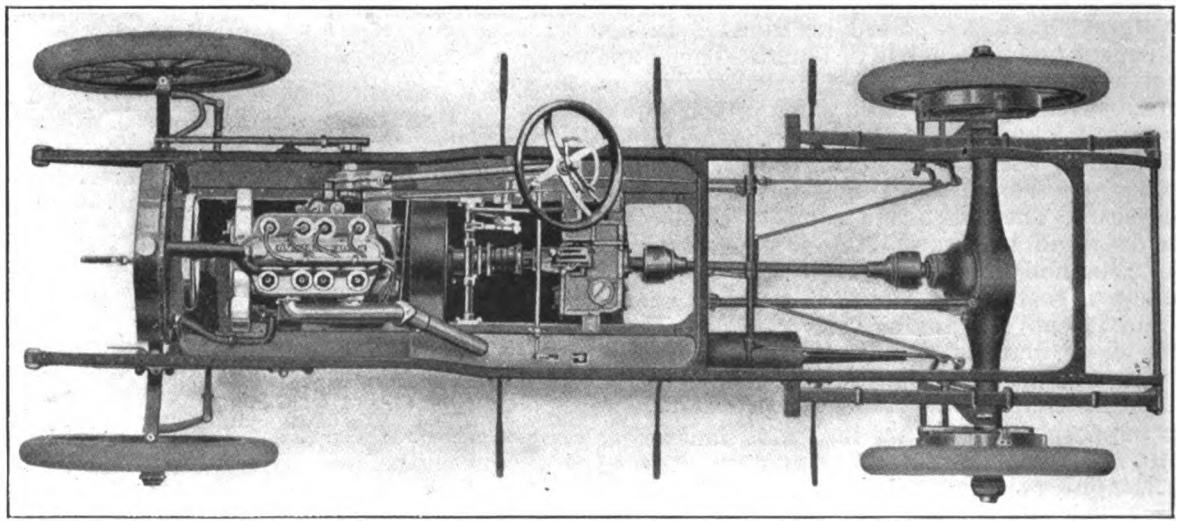
Pilot 40 Five-Passenger Touring Car. Price $2,000.

cylinders. Centrifugal pump, 17-in. fan on annular ball bearings.

Drive—Shaft, straight line. Double universal joints between clutch and transmission and between transmission and differential.

Ignition—Dual system. Eiseman Magneto and battery.

Lubrication—Automatic splash system.



vanadium steel. Three forward speeds and reverse.

Tread—56-in. or 60-in.

Wheels—Artillery type. Twelve heavy spokes of second growth hickory Q. D. Demountable Rims.

Wheel Base—Pilot 40, 120-in., Pilot 50, 126-in., Pilot 60, 132-in.

Equipment—Standard equipment includes Gray & Davis Electric Lighting and Starting System, pure

Chassis of Pilot 40.

Motor—Cast en bloc. Pilot 40, bore 4½-in., stroke 5-in. Pilot 50, bore 4½-in. stroke 6-in. Pilot 60, bore 4-in., stroke 6-in. Pilot 40 and 50 four-cylinder; Pilot 60 six-cylinder.

Horsepower—Pilot 40, brake test 53; Pilot 50, brake test 59; Pilot 60, brake test 67.

mohair top and hood, ventilating windshield, Warner Auto Meter, (Stewart & Clark Model C-1 speedometer, clock combination optional) Stromberg Carburetor, both bulb and electric horns, tire power pump for inflating tires and connected with flywheel when in operation. Five electric lamps, tool kit, tire

repair outfit, jack, Hind View Auto Reflector, Never-out License Brackets. Toe and robe rails on touring cars, tire irons on rear.

THE NEW HUDSON.

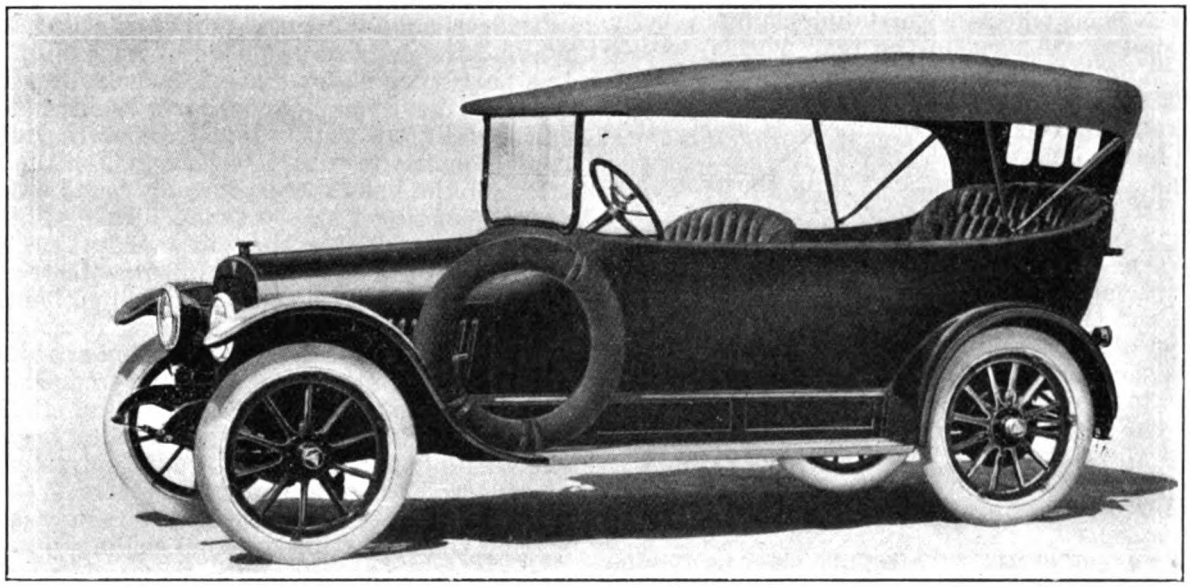
Final Evolution of Automobile Construction, Convenience and Lasting Quality.

Those who purchase a Hudson car do not buy an experiment. They are known and have been tested in every civilized country on the face of the globe, and in many that are far from being civilized. And it has not been found wanting in a single instance. Not a weakness or shortcoming, not a fault or criticism, has developed.

The 1916 model is a beauty, the lines being as graceful as the construction is scientific and the material of the highest quality. Meantime, the price for the 1916 new type Hudson has been reduced to $1,350, which means a drop of 23 per cent. in two years for a vastly improved car. The Hudson is probably the lightest six cylinder car on the market

quietness are of cloth composition, which has been proven to be the most satisfactory.

Water pump is of centrifugal type and of such size as to provide ample circulation of water.



Lubrication—Motor is lubricated by constant level splash system, with reservoir beneath the crankcase.

Oil level gauge is provided on the left of the motor, this gauge indicating the amount of oil in the reservoir.

Carburetor—The motor is equipped with a carburetor of improved type, with adjustment for low speed. One adjustable control valve attached to carburetor, controls hot and cold air, and also strangler. This valve is operated by a lever on the cowl-apron within easy reach of the driver.

Ignition—New, improved, patented, quick acting system. Dual ignition, that is, one system of the magneto type for ordinary running and another, with the dry batteries, used in case of emergency.

Starting—The motor is positively self-started, thereby doing away with the necessity of the start-

to-day, this meaning less fuel consumption, less general wear, and much longer lasting tires. Here follows some of the specifications:

Wheel base, 123 inches—left side drive—right hand (center) control.

Cylinders, 3½ inch bore by 5 inch stroke. Valves are of nickel steel and interchangeable.

Pistons are of special grade gray iron, annealed, ground, and with rings in place, are lapped in their respective cylinders.

Wrist pins are of nickel-steel tubing, hardened and ground.

Connecting roads are of special steel I-beam section, heat-treated to relieve all undue strain.

Crankshaft is of an original design, forged from special steel and heat-treated.

Crankcase proper is of aluminum. The upper half of the case carries the three crankshaft bearings so that, should it be necessary, the lower half of the case can be removed without disturbing the crankcase.

The camshaft is made of special steel, hardened and ground. Cams are integral with the shaft.

Timing gears are of helical type, and to insure

ing crank. The starter is operated by pushing a small foot pedal located on the left side of the gear shaft lever in the center of the car.

Lighting—All lamps are lighted directly from the generator when the motor is running. When the motor is not running, necessary current is supplied by the storage battery. This storage battery is automatically recharged by the generator. A small lamp is located on the cowl apron, above the instruments, for the purpose of illuminating them at night. All lights are operated by switch conveniently located on the cowl apron.

Clutch—It is of an improved noiseless disc type, self-contained in an oil-tight case, which is a part of the flywheel.

Transmission is selective, three speeds forward and reverse with direct drive on third speed. Transmission is bolted to the rear of the motor, making a unit power plant.

Power is transmitted from the transmission to the rear axle through a tubular propeller shaft, and two universal joints.

The front axle is I-beam type, the axle proper being a one-piece drop forging.

Digitized by Google

Wheel spindles are of nickel steel, heat-treated.

Pivot pins are of special steel, hardened and ground.

Positive lubrication of all bearing surfaces in the spindle head is provided by means of compression grease cups set in top of pin and in center of spindle. Leather dust washers are provided at all exposed joints.

Speedometer drive is effected by a flexible shaft from forward universal joint to indicator located in a conspicuous position.

Rear axle housing is of reinforced pressed steel which is much lighter and stronger than the ordinary combination tubing and cast housing type of axle.

The driving shafts are made of chrome nickel steel, heat-treated.

Front hubs and flanges are pressed steel securely clamped to the woodwork of wheels. Rear hubs are steel forgings.

Brakes—The foot brake is of external contracting type and the emergency brake is of the internal expanding type.

Wheels are of the artillery type. Ten spokes are used in the front wheels with 10 hub clamping bolts. Twelve spokes are used in the rear wheels, with 8 hub clamping bolts. Wheels are fitted with 34-inch by 4-inch demountable straight-side rims.

The frame is of special grade pressed steel. It is of extra heavy channel.

Springs are of semi-elliptic type in the front and three-quarter elliptic in the rear.

Steering gear is of the worm and gear construction. Worm gear and shaft are made of one piece from a special hardened steel.

Spark and throttle hand control levers are placed at the top of the steering column.

The gasoline tank is placed under the cowl with the filler in a very accessible position on the cowl-apron. The tank is tested under pressure to make sure that there is no leakage. Capacity of the tank is approximately 14 gallons.

Radiator is an improved honeycomb type, of large cooling capacity.

Trunk rack of latest type is furnished as regular equipment.

The Hudson is electrically self-cranking, and electric lighted throughout. The system is the latest and most improved in use and is especially designed for the Hudson.

The spark advance and retard is perfectly automatic and requires no attention whatever.

All lights are operated from the electric switch on the dash.

Electric starting and lighting switch is furnished with key that locks all lights in place and cuts off ignition and starting current so that lights cannot be tampered with or car started without this key.

FORD CAR USERS.

To Those Who Want Best Service and Continued Usefulness.

When the car comes in on a wet and muddy day nothing is worse for the tires than leaving the car standing on them, particularly on a stone or cement floor, for at the point of contact with the ground the tires have no chance of drying and the wet will speedily find its way through any small cuts and quickly cause havoc, a premature burst through rotted fabric being the result. Once the wheels are clear of the ground it is an easy matter to turn the wheels round to examine the tires for nails, flints, etc., that may be embedded therein without having actually punctured the tube. These should be removed and any cuts filled up with some one of the fillers used for this purpose.

Tires may, with advantage, be taken off every 2,000 miles and turned round, so that they will run in the opposite direction. This has been proved to give longer life, and, incidentally, that distance is quite far enough to run before taking them off, examining the rims for rust and dusting afresh with French chalk. They will be all the better for this attention. The jacking up of the wheels also enables one to test the bearings both easily and quickly, correcting any trouble in that direction almost at its inception. Nor is it necessary to spend a lot of money on patent jacks, some of which do not allow the wheels to turn, operating on the hub caps instead of the axles. Any carpenter or wheelwright will supply four wooden blocks about 4 inches square at the bottom, two 15 inches long and two 13 inches long for less than a half dollar.

It does not take three minutes to get all wheels up, and the car can be pulled or pushed off them in less than that number of seconds, and only having to drop about an inch no harm whatever is done. Incidentally the car is much easier to start under these conditions with top gear in, for the flywheel effect of the back wheels turning round is taken advantage of to get a good swing. This will be particularly appreciated in the winter months.

If Ford owners will experiment with the gasoline adjuster on the dashboard they will probably be surprised to find how far to the right it can be turned without adversely affecting the running of the engine after a few miles have been covered, thereby reducing the amount of gasoline issuing from the jet. If the throttle is slightly opened to correspond with the turning back of the gasoline adjuster, a very considerable saving can be effected. One must, however, put the adjustment back to the original setting when starting up from cold again, or even if a short stop is made, until thoroughly warmed up again. The farthest extent to which the screw can be turned without causing the engine to missfire through too weak a mixture will soon be found, and its position noted. There is not the slightest necessity to buy an extra air inlet for a car fitted with an adjustable jet to the carburetor.

It is almost impossible to close the gasoline tap fitted to the bottom of the Ford gasoline tank, but if a hole large enough to put one's hand through is made in the fender above the footboard on the off side of the car, the exact position being ascertained, it can then be turned off and on with ease. This is much better than relying upon the needle valve of the carburetor entirely, for it is not by any means unknown for a carburetor suddenly to commence to drip from no apparent cause while standing. If a piece of black patent leather is fitted over the hole with two small nuts and bolts, the appearance of the car is not spoiled in any way.

The Ford Company recommend owners to "go it easy," which is excellent advice from every point of view. A light car does not hold the road so well as a heavier vehicle, and must be treated with more consideration in consequence. Every Ford owner would be well advised to fit a speedometer if the car

Digitized by Google

be not so equipped when supplied. It is almost impossible to gauge one's speed with anything like accuracy without one, and it should not be regarded as a luxury, but a necessity, and the mileage recorder provides an excellent check on the miles per gallon of gasoline run, tire mileage, and general running. The owner of a car not so fitted never gives his car credit for having done the mileage actually covered, and will then often begrudge replacements undeservedly. The Ford is such an excellent high gear car that there is a great temptation to stay "on top" too long. This puts an unnecessary strain on the car, and broken crankshafts have been traced directly to this habit. The excessive strain causes "whip" which really reaches breaking point in a shaft not built to bear such abuse.

The engine will itself give notice when it requires to be decarbonized by its rough running and proneness to knock, but this is a job which many do not carry out with sufficient thoroughness, and they do not get the full benefit in consequence. While the cylinder head is off, if the protrusion around each spark plug is carefully examined, it will be found that this is often coated with a fairly thick film of carbon, so hard that it has to be chipped off, and if pains are not taken to remove this, overheating may easily be caused. The exhaust ports, too, get covered with a flint-like deposit requiring a special tool to deal with it. A piece of metal shaped like a screwdriver bent to a considerable angle at the "business" end will get into the corners where an ordinary screwdriver or similar tool would not go. The non-removal of this causes excessive heat around the valves. If, after decarbonizing, the piston tops, valve heads and cylinder casting around the valves are polished with a piece of wire brush used for cleaning files, the formation of fresh carbon deposits will be considerably deferred. An excellent gas tight joint can be obtained by carefully rubbing both sides of the cylinder head gasket with ordinary yellow soap, taking care to tighten the 15 bolts up gradually and equally. If the car can be left over night for the joint to settle down, so much the better.

The addition of a water accelerator to the Ford circulating system has been found by many to result in better running and less waste of oil and loss of water. Less than a cupful every 200 miles will suffice to bring the water to its original level. A sluggish water circulation is far reaching in the harm it may cause, and the above offers one way out of the difficulty. If the car owner will provide himself with a few tools not included in the usual kit, it is really surprising how independent of the garages he can be for small jobs.

The range of adjustment on the coils is so narrow that it is frequently a most difficult matter to obtain regular firing for long at a time, and those who experience any trouble in this direction will be well advised if they fit a master vibrator, which has such a wide range of adjustment and equal effect for all cylinders, instead of four separate vibrators, which it is a matter of great difficulty at times to operate alike. With the separate coils, missfiring is frequently caused when the light is switched on, and the adjusting screws would have to be altered to correct this, not always successfully, and then an attempt has to be made to find the original adjustment for use in the daytime. With a master vibrator, in all probability, no different adjustment would be required, and, if so, only to a very slight extent.

When grinding in the valves, it will sometimes be found that the tappet clearance is excessive. The running of the car can be considerably improved by closer adjustment. If a piece of very thick brown paper will pass between the tappet and the valve stem easily that will give all the clearance necessary for first-class running. Valve stem adjusters can be purchased for this purpose. If upon examining a valve a ridge is noticed around the face it will result in better running if the surplus metal is removed with a valve cutter, or skimmed off in a lathe, as the passage of the gases is considerably throttled otherwise. If a light spring is dropped on to the valve stem of sufficient strength to hold the valve off its seating, the operation of grinding is considerably lightened, as the valve has not to be lifted off its seating by hand, and the oftener it is lifted during the operation the better the result will be.

It is advisable to remove the detachable plate from the bottom of the crank chamber after the first 1,000 miles running, and at less frequent intervals later, to remove the foul grease that will be found to have settled there and to change the oil. Quite a lot of metal gets rubbed off the bearings of a new engine and settles there. It cannot be too often reiterated that the first few hundred miles should be covered at a comparatively low speed in order to allow all the bearings to get well run in, and owners must resist the temptation to see what the new car will do. A little restraint at the beginning will amply repay in the long run, and the car will not develop little rattles and general looseness anything like so quickly if the pace is kept down to 20 miles an hour as a maximum at first. To run any car at the mininum of expense requires a certain amount of thought and care expended upon it, but this is amply repaid in the results obtained. All the joints and bearings of a car require more attention when it is new, but if the necessary attention is given (and it does not take long to get round) the buying of renewals will be postponed almost indefinitely.

THE EMERGENCY BRAKE.

What It Is for and How and When to Use It Properly.

F. R. Hutton in The Club Journal of Philadelphia. —The discussion of the brakes for a motor vehicle would naturally divide itself into two parts. It is plain that there must be one brake which the driver uses all of the time, and whose use becomes semi-automatic so far as his muscles are concerned, or which requires so little time to think that the brake will be applied immediately upon the necessity to use it. Such a brake to be applied in an emergency might have claim to be called an emergency brake. In the second place the brake which is to control the car in an emergency external thereto must be always in condition to use. Hence, therefore, the brake used in service should be the one to be used in an emergency. From this point of view, and regarding the emergency as something external to the car, the service brake and the emergency brake should be the same thing.

There has arisen, however, the use of the term "emergency brake" as being a brake to be used in the case of an emergency or an accident happening to the service brake. In such an emergency, used

Digitized by Google

in this sense, there must be a brake to use when the principal or dependable brake has failed.

Those who recall the history of the early cars will remember that at first there was but one brake. This was universally applied by the foot because the hands were otherwise occupied. If one goes back far enough, the memory will unearth the foot brakes which would hold in only one direction, that is for the car going forward, while if the car started to go down hill backward the tendency was to unwrap the brake band and neutralize the pressure of the foot. Some nasty accidents resulted from this badly designed early type of brake and all modern brakes worthy of the name hold in both directions. The legislation of many states demanded the installation of two brakes, one of which to be supplementary to the foot brake already in service, and which, therefore, received the name "emergency brake," used in the second sense above referred to. It was convenient to make this second brake a hand operated device, and it received the form closely resembling the type of hand brake used on horse-drawn vehicles for many years. It was also made with a ratchet and dog detail, so that it could be used as a locking device to hold the car with the brakes set when the driver left his place and took his foot off the foot pedal. The muscles of the leg are the most powerful of the body; and a man using the extensors of the upper leg to straighten the knee can exert a pressure or produce a lift greater than he can do in any other way, and with less fatigue. For these reasons it would seem that the foot brake should be made in the design of the car to be the more effective of the two brakes so far as ability to stop the car is concerned in the presence of an emergency external thereto. The hand brake with its latch construction should only therefore be called an emergency brake because it is to be used in case of failure of the foot brake by reason of some accident thereto which may or may not be called an emergency. There used to be a general practice which still prevails in some cases to connect the hand brake with its detail of latch for locking with the mechanism which operated the clutch of the motor so that the clutch can not be put in gear with the hand operated brake locked on. This is now discontinued for the reason that it is often convenient to use the compression in the cylinders of the motor as a means of braking, and if the hand brake cannot be put on without pulling the clutch out of gear the hand brake could not be used on long grades as a supplement to the braking action of the compression. The hand brake is used by many drivers on long grades as it can be set in position and locked there. It is probable that even here, compression braking would be equally satisfactory and would save wear on the braking surfaces.

There is an opinion among certain designers that the foot brake should not be what they call "positive." This term as so used means that the operator may lock the wheels by means of his brakes so that they skid upon the ground. To prevent this they either allow the equalizing lever to be flexible enough to bend under a strong application of the brake, or they make the brake levers of small enough section to stretch, and still allow the wheels to slip. The hand brake, however, under the philosophy of design, is made "positive" so that with it the brakes may be applied with positive effect. For the reasons above indicated this philosophy is not believed to be as sound and defensible as that which makes the best brake which is to be depended upon and used in an emergency. As a matter of fact, both brakes in a well-designed car are powerful enough to exert the maximum retarding effect on a road surface upon which the tires will not slip when brakes are applied. This is an opinion held by many as a result of experience in the past on railways with the smooth tread on a smooth rail that the maximum retarding effect is produced when the wheels are just turning without slipping upon the rail. When the brake was sufficiently powerful to lock the wheels and cause them to skid on the track the train did not stop in as short a distance as when the other condition prevailed. Therefore, the brake levers are adjusted on this philosophy so that the brake cannot be put on too hard even with the maximum pressure in the train reservoir. It would seem that the same philosophy would hold always on a smooth or slippery roadway. There can be no objection to giving the driver the maximum retarding power on his foot brake so far as the designer is concerned, and then have him taught in operating not to use it all the time. A car of ineffective brake power is a menace both to those within it and to other users of streets and highways.

BATTERY HINTS.

Not New But They Must Always Be Borne in Mind.

Batteries must be carefully installed and securely fastened in position. No vibration of the cells in their containing box must be permitted, and play of the connecting straps must be prevented.

The cells must be readily accessible to facilitate the regular addition of pure distilled water and the testing of the solution.

The battery compartment must be kept well ventilated and drained and must keep out oil, water, dirt, etc. It should also be well coated, both inside and out, with acid resisting paint. A free air space must be left all round the battery.

Any spilled solution must be instantly removed by waste, wet with ammonia water, and the interior of the battery compartment kept clean and dry.

An open flame must not be brought near the battery, since a battery in use, or even when resting, gives off hydrogen, a highly explosive mixture being formed when the hydrogen is diluted with air.

Pure distilled water must be added at regular intervals and the solution maintained above the top of the plates.

Remove the plugs to add water and replace them carefully after filling, otherwise solution will be spilled when the car is in motion. Replace lost or broken plugs immediately.

Do not use tap or boiler water for refilling.

Use a clean non-metallic vessel to hold or store water.

Attend to the plugs and boxes regularly and replace broken or leaking ones.

In cold weather, add the water just before charging to prevent freezing, for water freezes at 32 degrees F., while accumulator acid does not freeze until the exceedingly low temperature of 4 degrees F. has been attained.

Density of Solution.

Ascertain the condition of the battery by testing the density of the solution.

Digitized by Google

Use a hydrometer, hydrometer syringe, or a discharge indicator.

Test after the water added has been mixed by charging.

The density of the electrolyte in each cell should be about the same.

The values should vary from 1.22 in a fully charged cell to 1.18 in a discharged cell.

Some makers give a greater range—1.22-1.15, and in two cases 1.12. The latter figure is contrary to good practice.

The variation is to be explained by the fact that the range in density is dependent upon the amount of the acid present compared with the bulk of the plates.

Never add acid except under expert guidance.

If acid must be added and there is no time to consult an expert, make up the acid to the same density as that in the cell.

Do not add acid of 1.22 gravity to a discharged cell.

Excessive water replacement indicates a leaky cell.

Charging and Discharging.

Ascertain the correct charging current and compare this with the reading of the car ammeter when the cells are on charge.

The normal charging rate should be about one-tenth of the capacity in ampere hours (continuous discharge, not ignition rate).

A low ammeter reading generally indicates a slipping belt.

If the belt is in order, examine the brushes on the dynamo. True up, but do not displace them, for the regulation depends upon brush position.

If the cells are in order, the charge is complete when the voltmeter registers 2.5 volts per cell, or 2 volts per cell with the cells supplying current and the dynamo disconnected.

Check some time after charging, as the reading is always higher just on the completion of a charge. Say after half an hour.

If outside charging is made use of, connect the positive battery terminal to the positive charging wire.

Test polarity of the charging mains by a voltmeter or by dipping the charging wires in water with a few drops of electrolyte added. Bubbles appear at the negative.

Use carbon incandescent lamps for resistance purposes.

Avoid overcharging or too rapid a discharge.

Connect an ammeter in the circuit to avoid excessive charging current.

Never discharge below 1.8 volts per cell.

Prevention of Troubles.

Terminals and connectors must be non-corrodible.

Keep terminals coated with vaseline.

Use anti-sulphuric enamel for all connectors and cable.

Doctor a sick cell by prolonged overcharging at a reduced rate on a charging board.

Consult the makers when in trouble.

Keep the cells in regular service and as fully charged as possible.

Fully charge a battery that has to stand idle, and give it a freshening charge at least every two months, recharging fully before using.

Remove all connecting wires if the battery has to stand idle for a lengthy period.

Burns and Stains.

Keep a bottle of ammonia handy in case of an accidental splash of acid. The instant application of this liquid neutralizes the acid and prevents a hole from being burnt in cloth.

Dip the hands in water, rendered strongly alkaline with washing soda, to prevent the skin smarting.

If acid enters the eye, wash well with water, warm if possible, and then put in a few drops of olive oil. Any oil, however, is better than none, and engine oil may even be used for the purpose.

SERVICE TO THE OWNER.

From a Paper Read Before a Convention of Service Managers.

By Charles Gould, Manager of Service, Maxwell Motor Co.—This question implies the existence of a definite and fixed policy used by all companies, although such a policy, of course, does not exist. On the contrary, the meaning of the word "service" as applied to the owner is varied in its interpretation. In fact we may say that "service" means something different to every manufacturer. Furthermore, as our interpretation of it relates to one service only and as we believe the discussion of any single company's policy would beg the question, we will take the liberty of changing this query to read: "What Should Constitute Service to the Owner?"

Service to the owner should embrace the following main components

1. Parts.
2. Repairs.
3. Supervised instruction.

Besides these, co-operation between manufacturer, dealer and owner is a necessary adjunct. Each has a very distinct duty, the performance of which alone makes successful service possible; and after endeavoring to define what we mean by "parts," "repairs" and "supervised instruction," we will state what we think these duties should be and the manner of their performance.

By "parts" we mean not only the matter of purchasing new parts to replace those actually worn out and the method of replacing defective parts, but also the rules which determine whether or not a part is defective, and for such as are found to be defective, the proper passing of credit.

There should be a sufficient supply of parts so located as to be at all times conveniently obtainable by the owner. There should be a well defined meaning of the word "defective;" this definition to be the result of judgment, which, though broad and liberal-minded, will impartially consider the manufacturer as well as the owner. This determination must of necessity permit the use of common sense in the judgment of particular instances, but the number of these particular instances should be carefully recorded as such and care taken to guard against their injudicious increase. Accidents, lack of oil or grease, driving ignorance and temperamental differences between owner and dealer are some of the things which service should not be called upon to cure.

In this very connection were the question asked, "Has the manufacturer been too liberal in his interpretation of the word 'defective' as applied to his dealings with dealer and owner?" would not the implied affirmation be forthcoming? Has the time come to strictly enforce the 90-day warranty or at least to so supplement it that the limit of broad in-

Digitized by Google

terpretation may be definitely fixed? "Free from defects in material or workmanship under normal use and service" seems to be a very definite phrase, but is the meaning of "normal" accurately understood?

When these questions have been squarely met and answered and a standard set up, the owner should unquestionably be entitled to replacement of all parts free of charge which are defective in material or workmanship, and for these reasons only and during 90 days only, or whatever the specified time may be. Making these replacements, or the passing of credit for a like amount, should be made contingent, however, upon the receipt of the defective parts, transportation charges prepaid.

By "repairs" we mean the provision of adequate facilities for the repair of parts, the making of necessary adjustments and inspection, the establishment of a definite rule in regard to the amount of free adjustment and inspection and the fixing of a scale of prices for certain classes of work.

Service to the owner should constitute these facilities and the rules governing their use. Not only should he be entitled to know beforehand the cost of work when the amount of it can be predetermined, but he should be given to understand in no indefinite terms the exact amount of free adjustment and minor repairs he can expect. To make this effective, there must be a well-equipped and a well-run shop. A careful and painstaking policy, leavened well with courtesy and a spirit of "nothing is too much trouble" should form a part of this shop's equipment.

Instruction constitutes a very important part of service to the owner. It should begin with the sale of the car in supplying him with complete information in printed form regarding not only the care and maintenance of his car, the proper method of ordering and returning parts, but also suggestions relative to all other matters which will lead to the fuller enjoyment of his car and to the keeping down of his cost of maintenance.

These instructions should be constantly called to the owner's attention by showing him, if possible, the exact rule the violation of which has made repairs necessary. At every opportunity he should be impressed with the fact that his car is a very valuable piece of machinery and that it requires a fair amount of care and attention. He should be shown that neglect is not only a poor substitute for this care, but made to see to what extent it has touched his pocketbook. So instruct him that he will share with you the knowledge that although his car will perform wonderful feats, it is not equipped with a brain, and by these instructions convince him that an ounce of prevention is worth more than a pound of cure.

It should be the duty of the dealer constantly to maintain a complete supply of parts. He should be guided absolutely by the company's policy in making adjustments and replacements and he should not only pass to the owner the same amount of credit which he receives from the company, but go even further in his interpretation of the meaning of the word "defective" and be more liberal in his allowance of free adjustment and minor repairs.

It should also be the dealer's duty to maintain a proper repair shop. He should make it his particular duty to insist upon a systematic inspection of the owner's car and it should be his earnest endeavor to instruct the owner in the proper manner of adjustments and minor repairs. While the latter may tend to curtail somewhat the volume of his repair business, it will be more than made up to him in increased sales and he will be rewarded also by a constantly growing number of satisfied customers. To properly enforce the policy laid down by the manufacturer, particularly where it is his clear duty to refuse free material or labor, he should keep a separate record of every car and the amount of service performed on it.

The manufacturer's duty should consist in establishing the rules governing service to the owner. It should also be his duty to see that these rules are rigidly enforced. He should conduct a systematic inspection of the dealer's stock of parts, his shop practice, accounting methods and the charges made for repair work. He should instruct the dealer in the method of best keeping such records, the inspection of which will reveal to him exactly the amount and kind of service the dealer is giving, and when this inspection finds the necessity of a change, the manufacturer should insist upon its adoption.

Before passing credit to the dealer, he should insist upon the receipt of the owner's name and address, and when such credit is passed to the dealer, the owner should at once be notified. Pride alone should teach the manufacturer the necessity of jealously guarding the method of his dealers in handling his product.

He should also do his part in keeping dealer and owner thoroughly posted at all times in regard to the results of his experience, and in order that this experience may consist of more than the information gathered by his representatives in the field, he should maintain a well-equipped service experimental laboratory for the purpose of adding to the general sum of mechanical knowledge, with particular reference to adjustments and repairs. The benefits of such work should be passed along by him to both owner or dealer. Any suggestions received from the owner or dealer should have his immediate attention, whatever their value. Full credit for such as may lead to an improvement, and the reason for the impracticability of the rest, should be courteously given.

The manufacturer should constitute himself the umpire of all disputes between owner and dealer and his decision should be absolutely final, and, although the owner should be made to feel confident that he will be accorded at all times just and fair treatment, he should be held strictly to account for any attempt at sharp practice. The policy of standing back of one's representatives will work out as successfully in the giving of service as elsewhere.

It would be the owner's duty to assist in every way towards properly and efficiently carrying out the service policies as outlined by the manufacturer. He should furnish all information necessary to the proper filling of orders and the issuing of credits. At the very outset he should be made to understand that it is not the dealer's nor the manufacturer's duty to write him for information which should have been part of his original order. He should not be coaxed too often to use the same kind of business methods when ordering or returning parts as are necessary in probably all of his business dealings. As the matter of service concerns him chiefly, he should be more than willing to co-operate, not only by calling the manufacturer's attention to shortcomings on its own or the dealer's part, but he should be ever willing and ready to make helpful

Digitized by Google

suggestions to the manufacturer and dealer, which in the final analysis will redound to his own benefit.

Finally, a service to the owner which is actually furnished by the dealer, under a systematic and well-defined policy laid down and supervised by the manufacturer, not only can be made the means of an enormous financial saving to all concerned, but also will create a well-founded feeling of satisfaction which the combined co-operation of dealer, manufacturer and owner will do much to foster.

CORD TIRES.

Their Construction and Some of the Advantages Claimed for Them.

At the Indiana section of the S. A. E., J. H. Wagenhorst of the Goodrich Tire Company, read a paper on cord tires in which he said:

Fabric Tire Construction.

In fabric tire construction the cloth or fabric is cut of a certain length and width to thoroughly envelop the core or form upon which the tire is built. One ply after another is laid until there are a sufficient number of plies in the carcass to give it the necessary strength and shape. Certain variations in length of circumference at the tread as well as at the bead are bound to prevail due to the shape of the tire. These variations in length are to a large extent, but not wholly, equalized during the building up process. The inequalities are, therefore, bound to cause disturbing forces in the tire, of which a more detailed account will follow. It is true that at certain parts of a fabric tire some material may be in tension while other parts are in compression, due to the inequalities spoken of. This tends to develop certain forces and heat while the tire is in motion.

Heat in Tires.

The general supposition is that heat in tires is due to road contact and skidding. To some extent this is true, but the percentage of heat from this source as compared to the real cause is small. As a matter of fact a very large percentage of heat comes from the inside or carcass of the tire. There are found to be variations in tension in each ply and between adjacent plies. The various plies not acting uniformly, the deflection due to contact with the road when a tire is in use, causes what is known as internal friction, which is practically the direct cause for the heat developed. The tire in use is constantly changing its shape or form at places of contact with the road, which requires a certain amount of energy; the greater the change in shape, the more energy is required and consequently the more heat developed.

Stone Bruises.

Whenever the order of curvature of the inner plies is changed from convex to concave under inflation, due to a severe blow, the inner plies are apt to break. In combination with the series of fabric cloth layers in the carcass will be found a certain amount of rubber by which these plies are stuck to each other, the power of adhesion being in a large measure in proportion to the quality of rubber used. The structure of a fabric tire is such that the warp and woof have no chance for elongation when severe blows are delivered. The result is that the inner plies cannot convey the shock over any great distance. In other words it is concentrated at or over the surface of an area about equal to the size of the object struck, the result being that the material is overworked and consequently breaks. How many know, however, that this has happened? No one removes a tire after a particularly hard impact, providing the inflation holds up and the tire has no apparent cut. The tire may not show the least sign of injury, yet on the inside will be found a broken strand in one, two or three plies. The tire has sufficient remaining strength to hold up for some time, during which wearing of the material of the remaining strands in all plies is going on until finally the casing gives way with no indication of defective fabric. When blow-outs occur on the tread, the cause has invariably been some severe blow by impact with a stone, block of wood, iron or any hard substance.

The Effect of Stone Bruises.

The body of a fabric tire is more rigid than that of a cord tire and consequently it will not bend through as large an angle without breaking. Impact tests have been made on fabric tires as well as on the cord tire to determine their relative strength. A pile driver was erected with a hammer of a certain weight, having at its bottom a projecting point about 2 inches long and 1 inch in diameter. It was found by dropping the hammer on a fabric tire and on a cord tire of the same size, that the cord tire would stand about double the blow before being injured.

If you should pull on a single cord in a cord tire, you would notice a slight movement along the entire strand from pin to pin. By releasing the pull quickly, the cord can be seen jumping back to its original position, showing that every portion of the cord does a certain amount of work when called upon. This action distributes the blow of stone bruises or shocks over a large area. The distance from pin to pin varies from 15 to 20 inches. To illustrate more clearly the effect of this length in distributing a shock, suppose an inch of this cord were subjected to a blow equivalent to 100 pounds. The cord being thoroughly anchored would have to resist all this in one inch. If the cord were 20 inches long, the shock would be distributed over 20 inches, each inch taking up a certain amount of the strain. The fact that the cords have freedom of motion and are embedded in rubber and also have a chance to elongate, makes them act as a dissipator of heavy blows.

Strength.

We have made numerous tests of cord tires and fabric tires, as to their comparative sternght, and find that the cord tires are considerably stronger. This is due to the fact that every cord is working more as a unit. We have frequently subjected 4-inch cord tires to 800 pounds hydraulic pressure without failure. These tests were made on tires that had already given 6,000 miles service.

Heat.

Cord tires running under the same conditions as fabric tires show a considerably lower temperature. This means a saving of horsepower by the use of the cord tire. The cord tire being more flexible offers less resistance to action and does not develop heat. In cord tire construction, with both plies laid under equal tension, there are no inequalities in tension and no excess work to be done in overcoming internal friction. It is claimed that the saving

Digitized by Google

in horsepower is easily 15 per cent., and the fact that cord tires do not heat up proves that the saving is directly in the tire.

To test the comparative load-carrying properties of fabric and cord tires, a hill was selected on which the grades were measured and it was found that with equal size tires a car carried 800 pounds more load at a higher rate of speed with cord tires than could be carried by the same car with fabric tires. In these tests the throttle of the car was fixed and not disturbed during the time the test was going on.

Repairs.

Cord tires can be repaired so well that the repaired portion is fully as strong as any other part of the tire. To prove this, suppose a tire has been cut or injured so that it is necessary to remove the cut or broken cords in order to make the repairs. The cords are taken out by stripping off enough of the tread to expose the cord between the two pins where the cord is looped. The bead covers are removed and the beads forced away from the tire far enough to allow the pins to clear, after which the broken cords are slipped off the pins. A repair may cover a space of several inches and include both plies if the injury is great enough to cut through both. Owing to the fact that the cord tires do not stretch, we keep what are known as cord sections. These sections are taken directly from tires made for such repair work. The cord section is fitted directly in the space whence the broken cords have been removed, fitting perfectly over the pins, as well as conforming to the original shape and size of the tire. The repaired section of the tire is then vulcanized.

In conclusion, I would say that cord tires have these advantages over other types: Greater engine efficiency; gasoline saving, which guarantees greater mileage; additional speed; quick starting; easier guiding, thus reducing the work of steering; greater coasting ability; greater strength; practical immunity from stone bruises; greater riding comfort and safety. All these advantages are due to two things. First, the equality of tension in all members of the cord tires, and secondly, the use of only two plies in absolute unison, which means that there is no work to be overcome due to inequality of tension in the tire. The only way that a tire of this kind can be made is by the use of a specially prepared cord. It is the nearest approach to the ideal construction, which as has been stated, should be a one-ply tire, as it has but two plies, and gives a tire of greater strength.

THE AUTOMOBILE ROUND TABLE.

Care for the Car Finish and Tires—Prompt Service and Touring.

From G. D. Crain, Jr., Kentucky.—The owner of a new car, especially if it is one that has just left the factory, should be particularly careful about allowing mud to get on the finish for a few days after he puts it into service. There is always a possibility that the varnish may be a little green, and in that event the mud is likely to leave a spot that will be very hard to eradicate, and will spoil an otherwise beautiful appearance.

A friend of the writer recently had an experience that illustrates this very well. He purchased an automobile and decided to drive it home from the factory. He had been very urgent about delivery at a certain date—the beginning of his vacation—and possibly matters were rushed some in order to get the car ready to run by the time specified.

The auto looked good, ran well and everything seemed to be fine, so that the motorist started on his 500-mile trip without misgivings. And, as a matter of fact, none were needed as far as the mechanical features of the car were concerned, for he made the trip easily; but oh, that finish! Where mud had splashed up on the fenders and hood, the best efforts of the garage people were unavailing; they got the mud off, but each spot was marked by a stain.

The owner tried all sorts of methods to remove the spots, but inasmuch as they were due to a finish that had not hardened perfectly, there was nothing to do but wait for them to wear off. By the time the first gloss of the finish had disappeared, the spots had become about the color of the remainder; but that took some time.

If there is any suspicion that the finish is not altogether dry, a wash in extremely cold water will go a long way toward hardening it. Some motorists recommend greasing the car all over, stating that mud and other foreign matter wash off easily with the grease, leaving the finish smooth and clean.

"Selling" the Dealer a Car.

"When I take a car in trade," said a veteran automobile dealer, one of the few really successful members of the trade in his town, "I am buying something—not the man who gets the new car. In other words, the automobile owner who comes to me wanting a trade is in the position of the seller; not of a buyer. He has something to dispose of—his old car. The dealer is buying something which is, comparatively speaking, poor merchandise, and which he must sell again in order to get his money out of it. It is dangerous business.

"Our experience has been such that this season we have practically eliminated out-and-out trade-ins. About the only way we handle second-hand cars is to put them on our floor and agree to sell them for the owner. We do the best we can with the car, and submit all propositions for his approval. This relieves us of all risk, and at the same time shows the owner what the dealer is up against when he attempts to rehandle a used car and make money on the transaction.

"Occasionally we have calls for used cars at just about the time we are dickering with a chap who has something that is in demand. We arrange for the delivery of the used car before we make the sale of the new one, and in that event turn the old machine over to the new owner immediately. But, in any case, we take pains to see that we are not going to be caught with a lot of second-hand stuff which must be sold again before we get our profits back.

"There is where most of the people who have started in the business and failed have lost their money."

Tires Still Give Trouble.

The person reading the announcements of the car builders, and noting the claims made for easy-riding qualities, secured by the use of cantilever springs, thick upholstery, oversize tires, etc., and who then turns to the ads of the shock-absorber manufacturers to see how they assist in making "all roads boulevards," may get the idea that one can drive as fast

Digitized by Google

as the engine will turn over, no matter what sort of going it may be.

But this is far from the case, and aside from the fact that some discomfort is experienced in even the best of cars in riding at high speed over bad roads, the fact that such going is extremely hard on tires ought to give the motorist pause. The springs and the upholstery and the shock-absorbers help to save the passengers, and good springs likewise are beneficial from the standpoint of the motor; but the tires get just as much shock and pounding as ever, and bad roads will soon show in ruined tires, if the latter are not considered in getting over the highway.

Good sense, as well as easy riding, suggests that even though rough roads may be negotiated at high speed with a minimum of discomfort, it is far better to take them at a moderate pace and save the tires.

Prompt Service Counts.

An automobile tire dealer who has the biggest end of the business in his town on tires and vulcanizing carries a considerable stock of sundries, but in spite of his popularity and pre-eminence on tires, he has never been able to do much with the merchandise end of the business. The explanation, which apparently has not been grasped by the dealer, is simply that it takes too long to get waited on in this department.

If a motorist wants a tire change ten miles from the store, he can phone in and have a man on the job in less than half an hour. If a car drives up in front of the store for gas or oil, the supplies are forthcoming immediately. The dealer has organized his business with prompt service along those lines in view. On the other hand, if an automobile owner is interested in a new specialty, and comes in to inquire about it, it takes so long for someone to disentangle himself from the other business of the concern that the interest of the prospective purchaser has cooled off considerably.

Having a stock of the right goods is only the first step in the direction of selling them; even following this up with good advertising and display work will not be sufficient; but the sales effort inside the store must be right, and that means that the customer must be waited on promptly by a salesman who is able to concentrate on that particular thing for the time being.

The possibilities of the sundries business are much greater than many dealers believe. As it is the customer usually comes in and sells to himself, without much help from the dealer or his sales force.

Touring De Luxe.

By "touring de luxe" reference is not made to any special style or luxury of the automobile itself, but to the convenience which is afforded by the great service organization which the industry has built up.

A few years ago the automobilist who started on a long tour felt as though he were taking things into his own hands. He was prepared to handle most any job that might develop in connection with his machine. He expected to have indifferent roads to tour over, inadequate information as to the best and shortest routes, and more or less difficulty in locating garages and getting gasoline and oil. It was considered a rather hardy autoist who was willing to set out on any extensive trip.

Contrast this with all of the facilities which are afforded at present. Not only is the motor car itself so thoroughly standardized that engine troubles are few and far between, but road information is practically complete, as is garage service. An automobilist with little or no mechanical knowledge can tour just as confidently as an old hand, and outside of knowing how to change a tire—which with demountable rims is not much of a job—about all that he need be able to do is to drive the car.

If some of the automobilists who toured ten years ago could go over the same ground now, with present advantages of car, roads and service facilities, they would certainly say, "Oh, what a difference just a few years make!"

Out of Gasoline.

From the Ohio Motorist.—Under the spreading chestnut tree a stubborn auto stands, and Smith, an angry man is he, with trouble on his hands. He cusses softly to himself and crawls beneath the car, and wonders why it didn't bust before he got so far. The carburetor seems to be the cause of all his woe; he tightens half a dozen bolts but still it doesn't go. And then he tries the steering gears and finds no trouble there, till wet with perspiration, he quits in sheer despair. He squats beside the road to give his brain a chance to cool, and ponders on his training in the correspondence school, and then he starts the job once more, until by chance it's seen the cause of all the trouble is he's out of gaosline.

Fire Precautions.

"One often hears the argument that heat causes expansion of the air in a tire sufficient to produce a blow-out," says P. W. Litchfield, Factory Manager, The Goodyear Tire & Rubber Co. "Many motorists thus excuse their habit of running tires under-inflated. Even experienced garage men advise that tires be run at fifteen to twenty pounds lower pressure in hot weather. We have to admit, of course, that heat does expand air and raises the pressure in a tire, but in its practical effect the rise in temperature is insufficient to cause even the slightest danger.

"To satisfy ourselves on this point we recently made an unusually severe test, using a runabout equipped with 33x4 tires. We selected a day, which according to the local records was the hottest June day ever recorded. The tires were pumped up to eighty pounds with the car standing in the cool of the garage. It was driven intermittently for about an hour, and when not running was allowed to stand in the sun. Then it was taken for a spin at forty miles an hour over brick and tarred wood-block pavements. On measuring the pressure we found it had increased just four pounds.

"As far as the welfare of the tire is concerned a difference of four pounds is really no difference at all. Tires are now built with such a high factor of safety that an increase in pressure of many times four pounds would not cause a blowout unless already ruined by overloading and under-inflation. We have often inflated up to three hundred pounds without any damage to the tire.

"The most serious variation in tire pressure is caused by leakage. Rubber is to a small degree porous and will allow air under pressure to leak through it. A certain amount of leakage through both tube and valve is normal and to be expected. Your pressure may maintain itself for a considerable time, but it is never safe to count on it. You cannot put it too strong that under-inflation, not over-inflation, is the condition to guard against."

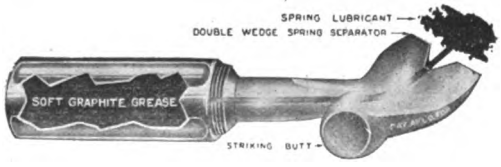
NEW AND INTERESTING THINGS IN MOTORDOM

Radico for Leaking Radiators.

This is a new compound which has recently been put on the market by the Radico Manufacturing Co., Box 887, Springfield, Mass. The illustrations will



give the reader an excellent idea of the appearance of a can of Radico and also show what the manufacturers call their "Silent Salesman Display Box," which is for the counter or show case of the supply dealer. It is claimed that with Radico anyone may make a metallic repair absolutely sure and permanent in 15 minutes. The Compound contains no acids or other injurious minerals which would eventually corrode the metal and cause other leaks. Motorists who have had trouble with leaky radiators, will appreciate this compound and it will undoubtedly have a large sale.

The Tomahawk Spring Lubricator.

The Tomahawk Spring Lubricator is an effectively simple tool for spring lubrication. Soft graphite grease, injected between the leaves of the springs

is the best known lubricant and will double the comfort and easy riding of your car, even if it is equipped with the best make shock absorbers. It eliminates the squeak, adds to their flexibility and allows free movement of the springs to absorb the shocks. Each application is good for 1,000 miles. It is very simple to operate and made of the finest drop forged steel hardened and nickel plated. Graphite grease greatly exceeds oil, as a spring lubricant which is too thin in body and will creep out and be absorbed by the dust and dirt that accumulates around the springs. It is easily washed out and evaporates. The price of the tool is 75 cents and is manufactured by the Charles W. Manzel Co., 307 Beard Avenue, Buffalo, N. Y.

Edison Day Prize Contest.

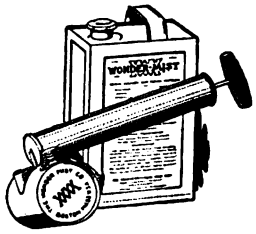
In conjunction with the celebration of Edison Day, October 21 this year, the thirty-sixth anniversary of the invention of the electric incandescent lamp by Thomas A. Edison, a nation-wide prize contest for boys and girls has been inaugurated by the Edison Lamp Works of the General Electric Company. Thirty-three grand prizes and 2,000 smaller prizes amounting to $2,500 are offered, and the conditions are such that either boys or girls may compete with equal chances. The contest will be carried on in co-operation with lighting companies and dealers all over the United States. The contest opens 12:01 a. m., Tuesday, Sept. 21, and closes 12:00 midnight, Thursday, Oct. 21, 1915.

The first prize for boys is a $275 Indian big twin motorcycle and for girls is a $200 new type Edison diamond disk phonograph with $75 cash for records; the second prize for boys is an $80 Evinrudo detachable rowboat or canoe motor, and for girls is an $80 order on any jeweler for a choice of jewelry; the third prize for boys is a $47 Old Town "Octa" 17-ft. canoe, and for girls is a $47 Parisian ivory toilet set; and so on down through a long list of jewlery, musical instruments, cameras, sporting goods, etc., for the thirty-three prizes. Each of the 2,000 boy or girl contestants that stand next highest will receive an Eveready fountain pen flashlight. Each prize is not awarded to one boy and one girl contestant, but the first prize to one boy or one girl, and so on. The boy or girl winner also has the privilege in each case of accepting the cash equivalent instead of the prize.

The conditions of the contest provide that each entrant must be under 18 years of age, and live in or near a city or town having electric light, in which a distribution of the cards for crediting Edison Mazda lamp sales can be made. The contestant has to secure from the local lighting company or agent for Edison Mazda lamps an official contestant card and the number of printed order cards desired, on which the contestant's full name and address should be signed in the space provided. Next the cards have to be distributed by the contestants during the time authorized to users of electric light in homes, stores, factories, etc., who can be induced to replace old style carbon incandescent lamps with modern Edison Mazda lamps, or who contemplate purchasing a new supply of lamps. The purchaser fills in his order for Edison Mazda lamps on the card, which can be returned to the local lighting company or Edison agent by the contestant, or mailed in or delivered personally by the purchaser during the stipulated period, from Sept. 21 to Oct. 21, 1915. Sales to individuals or firms holding contracts for Mazda lamps will not count, nor will free renewals.

The points of the contest are counted by watts, the current consumption of each new lamp being given in watts on the sticker. An order for one 10-watt lamp would credit the contestant with 1x10=10 points; four 25-watt lamps would make 4x25=100 points; three 40-watt lamps, 3x40=120 points; five 60-watt lamps, 5x60=300 points, and so on, the total number of points on the contestant's orders constituting his or her score.

After the contest is closed, Oct. 21, the lighting companies and Edison agents will total and turn in all the cards to the Edison Lamp Works of the General Electric Company, where they will be sorted and counted. The contestant, boy or girl, whose name appears on order cards totaling the highest number of watts, or points, in lamps sold will receive the first prize; the next highest, the second prize, and so on through the list. In case of a tie by two or more contestants, each one will receive the prize. This rule applies to all prizes except in the case of flashlights. The prizes will be distributed by the Edison Lamp Works of the General Electric Company just as soon as the cards are counted and the winners determined. Scores will be counted only on a basis of retail sales of Edison Mazda lamps through regular appointed agencies. Standard package quantities will, however, count in such sales. No prize will be awarded to any employe of the General Electric Company, of any lamp or of any lighting company.



Change in Name.

The corporate name of the O'Neil Tire & Protector Company of Akron, Ohio, has been changed to the O'Neil Tire & Rubber Company, and all in the trade who are dealing with this concern should bear this fact in mind.

Wonder-Mist.

The Wonder-Mist Company of Boston, Mass., after a great deal of experimental work, both in the laboratory and in practical use, introduced Wonder-Mist to the motor trade some two years ago. Wonder-Mist is entirely free from acid, grit

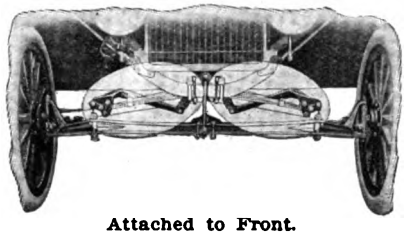
or any other injurious substance, is non-inflammable, non-combustible and non-poisonous, and is sold, under a money-back guarantee. It contains no gum or wax to necessitate a backbreaking amount of rubbing or to fill the corners with an unsightly deposit, but is applied with a sprayer which distributes a fine mist evenly over the surface to be cleansed and is consequently easy and economical to use. A slight polishing with a piece of cheese cloth then cleanses the surface and restores the brilliancy of the finish.

Besides it cleans and polishes furniture, woodwork, ornamental bronze, iron, floors, marble, dark leather and linoleum and is fast becoming a household as well as an automobile necessity.

Pedal Lock for Ford Cars.

This lock affords the owner of a Ford car absolute protection against theft, as it locks the clutch pedal in neutral, so that the motor may be started but the car cannot be operated. This lock can be put on the car by anyone in two minutes and it becomes a part of the car. There are no holes to drill. The lock fits in place of the lower left hand bolt in the base of the steering column. In some of the larger cities we hear reports of ten Fords stolen in one day, and when these cars are recovered, which is seldom, they are always damaged more or less. Many use a lock on the coil, but this does not positively lock the car, as with one end of a wire attached to the magneto terminal on the front of the dash, and the other attached to the base

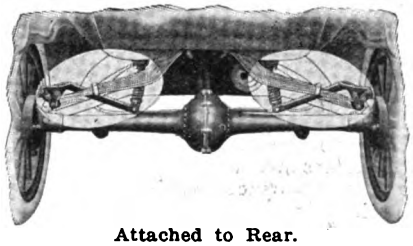
A Reliable Lock.



of the vibrator on the coil, the car may be operated, but with the lock there is no possible way for a thief to run away with the car. This device sells for only $1.50, and all inquiries and orders should be addressed to the Commercial Manufacturing Co., Commercial Building, Cleveland, Ohio.

Speedometer Parts for the Trade.

A large line of speedometer parts including swivel joints, flexible shafts and fibre gears for every speedometer on the market is manufactured by the Ogden Manufacturing Co. of Columbus, Ind. Their product is of superior quality and their prices are low. Proprietors of repair shops, dealers and jobbers should write for quotations and all such correspondence will have prompt attention.

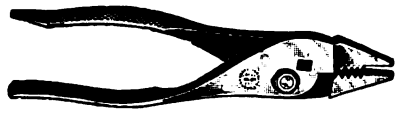


Easy Riding for Ford Cars.

Flexlevers are as their name indicates, a system of flexible levers which makes the Ford car ride like a high priced car. They prevent practically all vibration and overcome the disagreeable rebound, saving that lame back and making long

Attached to Front.

tours a pleasure rather than a hardship. They do not let jolts get into the car; they are absorbed immediately, thereby saving an immense strain on the mechanism of the car, reducing tire expense, thus saving their cost many times over in the wear and tear of the car. They work equally well at all speeds, and are essential on all kinds of roads. They do not allow any side sway of the body, or affect the steering of the car in any particular. They require no special machin-



Attached to Rear.

ing to attach, and the complete set of four can be attached in thirty minutes without the removal of wheels or jacking up of the car. There are no wearing parts to get out of order, no caps to lose or rattle, no lubrication is necessary, and when attached properly will last the life of the car. Sold subject to thirty days' trial and if not found strictly as represented and perfectly satisfactory, money will be refunded. They are made by L. P. Halloday Co., Streator, Ill., as are also the tire holders for Ford cars, illustrated herewith.

"Red Devil" Automobilist's Plier.

A handy vest pocket automobilist's combination slip joint plier with a Prest-O-Lite tank opener in the jaw is gotten out by Smith & Hemenway Co., Inc., 179 Chambers Street, New York City, manufacturers of "Red Devil" tools. It is a nickel plated drop forged steel tool and is only 5 inches in length, vest pocket size. The handles are milled and shaped to assure a firm grip. It is accompanied by a two years' signed and sealed bond, guaranteeing two years' satisfaction to the user, or a new tool is replaced free of charge. It comes in a leatherette case. The reason that the price is kept within practical limits is made possible by enormous output. It has proven beyond experiment that it is a highly practical tool for gripping bolts, nuts, pipes,

Vest Pocket Pliers.

screws, wires, etc. The specially designed thin nose permits use in close places, where an ordinary pair of pliers is too clumsy. In spite of these features, it retails for only 60 cents, and is said to be well worth the investment.

The Stewart Handy Worker.

This is a remarkable combination tool which is described by the manufacturers as a complete repair outfit in itself. This tool combines in one the following appliances, a strong practical anvil; a powerful vise, up to 4½ inches; width of jaw 4 inches; a sure-grip steel pipe vise, up to 1½ inch pipe, a Corundum grinding wheel 5x1 in.; a drill press with two drills; a metal cutting wedge and driving mechanism of three speeds. This mechanism operates a grinding wheel, a small circular saw, buffing wheel and many other similar tools. The entire outfit sells complete for only $12.50 and it is particularly adapted for use in small repair shops or public and private garages. Send your orders or write for full particulars direct to the manufacturers, The Chicago Flexible Shaft Co., 586 North La Salle St., Chicago, Ill.

A Convenient Oil Tank.

Of interest to the motorist who wants to know where his next gasoline is coming from is the new Q. D. (quick delivery) Gasoline Tank body for Ford cars made by the Ohio Welding and Manufacturing Company, of Cincinnati. Oil companies whose service is A. No. 1 must provide a method of transportation of gasoline and oil quickly to the garage

A Convenient Oil Tank.

or owner that requires a supply in an emergency. This outfit fills the bill. The 100 gallon tank with extra cans of lubricating oil when required makes just the right load for Ford cars. Tank complete can be attached the first time in an hour or two, and after that it requires not more than five minutes to attach or detach. This means that car can be used for a double purpose.

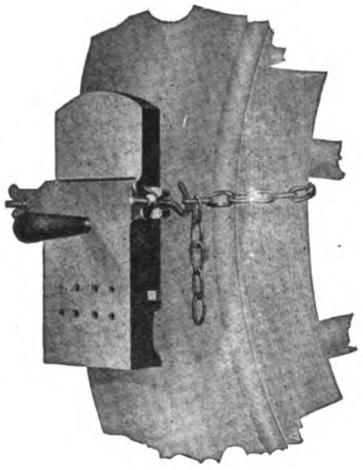
Firestone Annual Convention.

Thursday evening, September 30th, saw the close of the Annual Sales Convention of the Firestone Tire and Rubber Company at Akron, Ohio. For three days Branch Managers and Salesmen from every branch in its world-wide organization attended the various activities scheduled for the annual event. Every State in the Union and six foreign countries were represented. Five hundred men constituted the total attendance.

In this intimate study of business conditions in general and the tire business in particular these men gained a large amount of invaluable information. This information will in turn be given by each salesman to the customers in his territory. Thus through the days of intensive study and generous exchange of ideas the tire user is the ultimate gainer. It all results in better service for mortorists everywhere. Furthermore, it means a more up-to-date and better informed organization.

The men in attendance saw at the home plant in Akron, five large additions under construction—additions that will provide over seven acres of additional floor space and which will allow an increase in the output of Firestone pneumatic tires, from 7,500 to 12,000 per day.

The social side of this convention was not neglected. Dinners and outings at the Lakes around Akron, theater parties and banquets at local hotels featured the entire week. Conviviality and good fellowship were dominant during the entire progress of the convention. Company officials unanimously agreed that in point of attendance, interest aroused and results accomplished it was the biggest and most successful convention ever held by the Firestone Company.



Live Specialties for Car Owners and Garages.

The National Motor Supply Company, 5602 Euclid Ave., Cleveland, manufactures a line of specialties for motorists which should interest every one of our readers. They have recently brought out

National Air Jack.

the National Air Jack, illustrated herewith. This jack utilizes the tremendous power which can be exerted by the use of air. To use the jack, just put it under your car, attach a hand or power pump to the end of the hose, and up goes the heaviest car and stays up until the air is released. The jack cannot slip, as it has a safety automatic locking device which holds the car indefinitely for winter storage or for a short time. The jack cannot sink into the ground on account of its large base, and it has many advantages which the manufacturers would like to demonstrate. To introduce this jack, they are offering to put it out on ten days' free trial and if not as represented they will absolutely refund the cost of the jack. This device

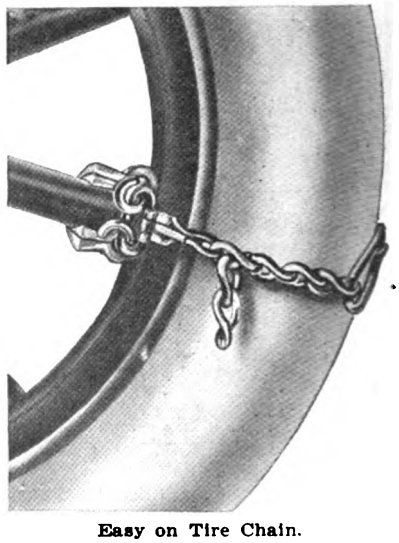
Wizard Automatic Steam Vulcanizer.

is very compact, being only 11 inches high when closed, and the price by parcel post is only $6.00, prepaid. No doubt many of our readers will accept the generous offer made by the manufacturers of this jack. The same company manufactures the Wizard Automatic Steam Vulcanizer for car owners, also illustrated herewith. This vulcanizer is curved to fit both tubes and casings of any size. The fuel used is gasoline and it burns with a blue flame, without any smoke. This vulcanizer is especially useful for roadside repairs, and it will soon pay for itself by saving your ruined casings and by filling the cuts with new rubber, making the shoes last twice as long. This article will also be sent on ten days' free trial, on receipt of the price, which is only $3.50, prepaid. The National Motor Supply Co. is anxious to trace the inquiries obtained from this publication and readers are therefore urged to use the coupons attached to their advertisement in this issue of our magazine.

An Attractive Engine Offer.

Many garages and repair shops throughout the country are putting in gasoline or kerosene engines for power and all who are interested in prime movers of the smaller sizes, will also be interested in the latest engine offer which has been made by Ed. H. Witte, of the Witte Engine Works, 2499 Oakland Avenue, Kansas City, Mo. Mr. Witte offers to put out his engines on sixty days' free trial to prove their big value. Every Witte engine is backed up with a five year guaranty, which certainly means something, as Mr. Witte has been manufacturing gasoline engines for twenty-eight years. His line for the automobile trade includes gasoline, gas, kerosene, and distillate engines, from 2 H.P. up to 22 H.P., and the scale of prices is remarkably low, running from $34.95 for a little 2 H.P. engine up to $359.80 for a powerful 22 H.P. engine. Readers are urged to write direct to Mr. Witte at the address mentioned above for his free book, and also for full particulars on the new liberal offer referred to in this article.

Creditors Buy McIntyre Assets.



The creditors of the W. H. McIntyre Co., which made the McIntyre car and Imp cyclecar in Auburn, Ind., and went into bankruptcy some time ago, have bought the propertv for $50,500. A new company has been organized under the name of the DeKalb Mfg. Co.

Less Horse Cruelty.

Humane societies of Illinois are in danger of going out of business because of lack of complaints. With the rapid reduction in the number of horses and the institution of motor cars complaints of ill treatment of these horses, which in the past furnished the bulk of the business for the humane agents, the occupation of the latter is nearly gone. Very few horses are now used for transportation purposes. The great majority are on farms where they receive the best of care.

Improved Easyon Tire Chains.

The Leather Tire Goods Company of Niagara Falls, N. Y., announces that they are now making deliveries of their 1916 Easyon Chains which have been improved in several respects. The new chains have a metal fastener for attaching to the spokes which is absolutely unbreakable and is covered with leather so that it cannot injure the paint. The cross chain where it comes in contact with the middle of the tire is smoothly rounded so that it cannot injure the rubber and the chain portion being made entirely of welded links is unbreakable under any condition. Most automobile owners carry chains with them only in order that they may be sure they will not get stuck on the road. Easyon Chains are especially valuable for such persons for they can be applied in a moment even when stuck in the mud or snow and will give excellent traction on any sort of road surfaces. They also have the advantage of being more durable than ordinary chains and it costs

Easy on Tire Chain.

less and is much easier to renew the cross members. Easyon Chains are packed a set of 8 in a bag, 4 for each rear wheel. They are made in two sizes, small size, which fits tires up to 4 in. cost $3.20 per set; large size, which fits tires from 4 to 5½ in. inclusive, sells at $4 per set. The chains will be delivered parcel post at these prices to any part of the country.

One Million for a Patent.

A million dollars for basic patents of the Dixie Magneto was paid recently by the Splitdorf Electrical Company of Newark, N. J., to the Sumter Electrical Company of Sumter, S. C., which controlled them through the invention of their president, Charles T. Mason. Rarely has such an immense sum of money figured in the transfer of patents, but the Splitdorf Electrical Co., now establishing a world-wide reputation as the largest manufacturer of electrical units, considers itself fortunate in the acquisition of the valuable rights to the Dixie features, which are playing such an important part in the world's ignition field. The Splitdorf Electrical Company is building as high as fifteen hundred Dixie Magnetos daily—single cylinder, two cylinder, fours, sixes, eights and twelves to meet the tremendous demand. It is the utter simplicity of Dixie Magneto construction combined with its extreme effectiveness that has brought the Dixie so quickly into the limelight as 20th Century Ignition.

Car With Four Wheels Off Ground.

Here is a picture of an incident in the recent Elgin Race. Traveling at such terrific speed that merely going over the brow of a little hill will hurtle the whole car into the air is test enough of the strength and resiliency of rubber tires When the machine hits the ground again, it bounces down with all of its 2,500 pounds at the rate of about 95 miles an hour. Both Anderson and Cooper used, with the utmost satisfaction, the Silvertown

All in the Air.

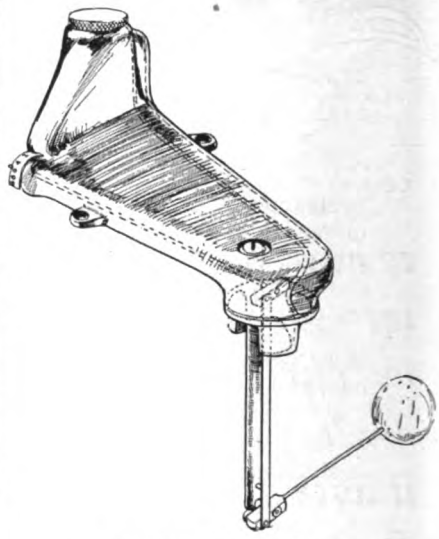
Cable constructed tire, made by the B. F. Goodrich Company, Akron, Ohio, under the Silvertown Patent. Cooper won the first day with Anderson second, while on the following day the order was just reversed.

The Silvertown Tire has won every important race this year and it is used by the drivers not only on account of its great speed and resiliency, but also because it is safe.

Salaam Cigarettes With Initials.

Many fastidious smokers like to have their initials or monogram engraved on their cigarettes, as it gives the little individual touch that makes you stand apart from the rest. The Salaam Cigarettes are made of the finest Egyptian tobacco, delightfully delicate, with splendid aroma appreciated by all connoisseurs of true Egyptian cigarettes. The manufacturers of these cigarettes are ready, at a nominal price, to send you a supply with cork, plain, silver or gold tips with your initials in block, script, or Old English type neatly engraved on each cigarette. These cigarettes will be sent parcel post prepaid at $2 per hundred including the initials, to any address in the United States. Send your orders and inquiries to T. Chalkiadi & Co., Inc., 503 A, Fifth Ave., New York City.

A Campaign to Consumers.



The Warner Auto Top Company, 1646 Central Avenue, Cincinnati, Ohio, which is an old and reliable concern, will hereafter market their product on an entirely new plan. They have been manufacturers of automobile accessories for a number of years, but heretofore they have always sold their goods to distributors, who in turn sold them to the consumer under their own private brand or trade mark. Realizing that by this method, they have been merely making goods for someone else to build up a reputation on, they discontinued all their contracts with these distributors September 1st, and they have now launched a campaign direct to consumers with the intention of establishing Warner Auto Upholstery as a standard article on the market. They will sell their covers direct to the trade under their own name, as manufacturers. By thus eliminating one large profit which formerly accrued to the distributor, they are able to place these goods on the market at a lower cost to the consumer and a larger actual percentage of profit to the dealer than heretofore. This is something which ought to vitally interest all readers, whether they are individual car owners, or dealers. An interesting catalogue will be sent to any subscriber who will take the trouble to write for it.

Repair Parts for Ford Cars at Cut Prices.

Many dealers and repairmen will be interested in the line of repair parts for Ford cars which are offered at cut prices by the Grossman Auto Parts Company of White Plains, New York. They are sending out a price list which they would be glad to mail to any of our readers who will take the trouble to ask for it. Their line includes differential ring gears, differential pinion gears, front radius rods, rear axle shafts, driving shafts, plain piston rings, triple piston rings, front springs, rear springs, connecting rods, and a large list of other parts at surprisingly low prices.

The Apex Fillometer.

We illustrate a new device called the Apex Fillometer. This is a gasoline tank filler and gauge combined which fastens permanently in place under the cushion, and the gasoline tank can be

Gasoline Tank Filler.

filled without the driver and passenger getting up from their seats. The meter is easily read from the driver's seat and anyone can install the Fillometer in two minutes with a screwdriver. The price of the complete outfit is $4.50 and it is manufactured by the Apex Electric Mfg. Co., 1410 West 59th St., Chicago, Ill.

New Gemco Specialties.

To supply a popular demand the Gemco Manufacturing Co., of Milwaukee, Wis., have decided to add to their line of individual bumpers for the Dodge, Maxwell, Buick, Studebaker, Packard and Reo cars, and also a new specially designed bumper for the 1916 Cadillacs. These bumpers are of "Gemco" standard construction, modified to exactly fit the individual cars for which they are designed, and we understand that all of these bumpers are now ready for deliveries. The 1916 catalog of the Gemco Mfg. Co. will be ready for distribution November 1st, and will show a number of new accessories. Any of our readers who may be interested to receive this catalog may do so by notifying the company.

The Mandel Limosette.

This is a flush, snug fitting top, made of wood, metal and glass for the Ford roadster and touring car. It is equipped with an automatic rain vision windshield, electric dome and handsome cowl dash. It has full length doors which operate with one handle, and the generous overhang in front accentuates the length of the Ford. These tops which are luxurious in appearance are built exclusively for the 1913, 1914, and 1915 Model Ford cars. They can be attached in less than an hour, and they add only about 40 lbs. to the weight of the roadster and 75 lbs. to the touring car. All inquiries and orders should be addressed direct to the manufacturers, the Mandel Limousine Company, 1453-1455 Congress Street, Chicago, Ill.

Keep Your Car Like New with JOHNSON'S PREPARED WAX

"I'm ashamed to be seen getting into such a shabby car. Why don't you polish it with Johnson's Prepared Wax? We've used it on the floors and furniture for years."

It forms a thin, protecting film over the varnish adding years to its life—it covers up mars and scratches—prevents checking, and imparts a perfectly hard, dry, glass-like polish which

Will Not Gather Dust

Johnson's Prepared Wax polishes and finishes in one operation. It is in paste form—clean and easy to use and economical. It is conveniently put up—always ready for use—no tools or brushes required—all you need is a cheese cloth rag.

"Sheds Water Like a Duck's Back"

The heaviest rain will not dim the mirror-like polish that Johnson's Prepared Wax gives your car. Use it also on your wind shield for clear vision and on the leather upholstery—it livens it up and acts as a preservative.

Makes a Wash Last Four Weeks

Johnson's Prepared Wax is a boon to the man who takes care of his own car. The tiresome task of washing is reduced to the minimum. One user writes us, "It makes a wash last four weeks instead of one." An occasional application will keep your car like new, increase its market value, and give you the prestige that follows the appearance of prosperity and class.

Send 60c for 1 pint by Parcel Post prepaid—enough for a season's use—or mail coupon for a trial can—sufficient for one polish on a large car.

A Welding Outfit for Only $42.

Every up-to-date automobile repair shop ought to have an oxy-acetylene welding outfit, and those who have not already installed an equipment of this character, will certainly be interested in the Waterhouse Complete Welding Outfit which is offered for only $42. This outfit is so small and compact that it occupies very little space in the shop yet it is guaranteed to be absolutely efficient and reliable. Readers who are interested should write for prices and full particulars to the Waterhouse Welding Company, 16 Pelham Street, Boston, Mass.

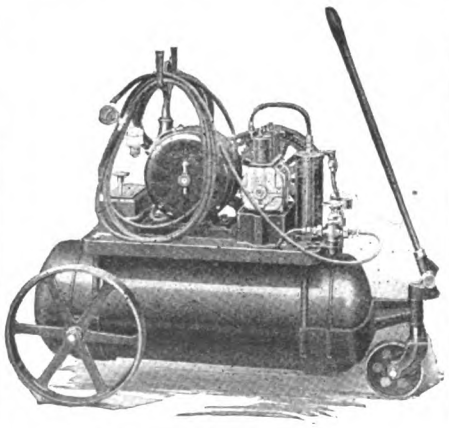
For Brakes and Clutches.

The efficiency obtained from brakes and clutches depends largely upon the proper countersinking of the rivets retaining the friction material. Ordinary tools are not satisfactory as ragged and uneven holes are likely to result. Stevens & Co., New York City, has perfected a set of countersinks for this work that is not only inexpensive but cut a clean and accurate hole. The set consists of three sizes, 9/16, ½ and 13/32-inch, these being used with Nos. 7 to 11 inclusive flat head rivets as well as with rivets with countersunk heads. As the shank of the tools is 5/16-inch in diameter they can be used in a drill press or hand drill. The set retails for $1 but single sizes are marketed. Stevens & Co. is also manufacturing six different assortments of brass and iron wood screws, brass and iron machine screws with nuts, bolts and copper rivets and burrs. These are marketed singly or come packed in a strong cardboard box. The sizes are particularly adapted to motor car repair work.

Now Made in America.

Among the many pre-conceived notions which have been dispelled as a result of the European war, not the least well grounded was the belief that it was impossible for American shops and American workmen to produce anti-friction bearings equal in quality, precision and uniformity to the imported bearings. It has been said that American mechanics were not temperamentally adapted to the quantity production of high-precision bearing parts over long periods. However, necessity has ever been the mother of invention—and the shutting-off of the supply of imported bearings created a situation in American industries which demanded relief. And American mechanical genius has proved equal to the emergency. The preliminary stages in manufacture having long been passed, enlargement of productive facilities consisted simply in the getting together of the men and machinery and materials necessary for operation on a larger scale. This extension has been in progress for several months and will continue so long as the demand for "Norma" Bearings promises to exceed the supply. The Norma Company now has a most efficient, completely equipped and up-to-date ball-bearing factory, turning out thousands of bearings daily in every way equal to the high-precision imported "Norma" Bearings which introduced a new standard in America. And this factory is being steadily enlarged and increased in capacity, to keep pace with the growing demand for speed bearings of the "Norma" standard.

Automobile Trouble Charts.

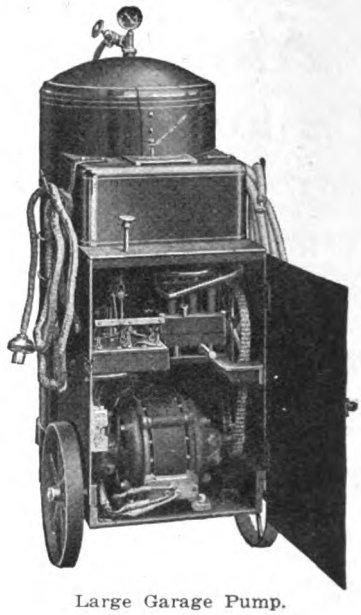


These charts are the most compact self-educators ever published and are sold at such low prices that they are within reach of all. They are practical, timely and authoritative as all have been prepared by a recognized authority on automobiles with an experience dating to the inception of the industry in this country, including practical shop work as well as design and construction. These charts are invaluable to all who motor. They make ideal wall charts for schools, clubs, garages and repair shops. These charts cover engine, ignition, carburetor and lubrication troubles, and car owners can procure any particular subject they wish by sending to the publishers The Norman W. Henley Publishing Co., 132 Nassau Street, New York, and enclosing 25 cents, or any five will be sent on receipt of $1.

Audel's Automobile Guide.

This is a standard work of reference for automobile owners, operators and repairmen. It contains a large number of questions and answers and illustrations in regard to the parts, operation, care, management, road driving, carburetors, wiring, ignition, motor troubles, lubrication, tires, etc., in fact everything connected with the mechanism of an automobile. The book contains a section on self-starters and lighting systems. The price is $1.50 postpaid, in leather binding, pocket size, and the publishers are anxious to send a copy for free examination to any one who doubts the usefulness or value of this book. Free examination of the book may be obtained by using the coupon which is attached to an advertisement appearing in this issue of the Automobile Dealer and Repairer.

Kellogg Garage Pumps.



The Kellogg Manufacturing Co. of Rochester, N. Y., have just issued a new folder illustrating and describing their line of Electric Motor Driven Garage Pumps. The models vary from a small stationary plant with a two-cylinder pump for the private garage to a large portable plant consisting of a 1 H.P. electric motor, driving their latest model 6-cylinder pump mounted in a portable

Kellogg Portable Pump.

unit with a large air storage tank, which holds sufficient air to take care of the requirements of a large garage for half a day without replenishing.

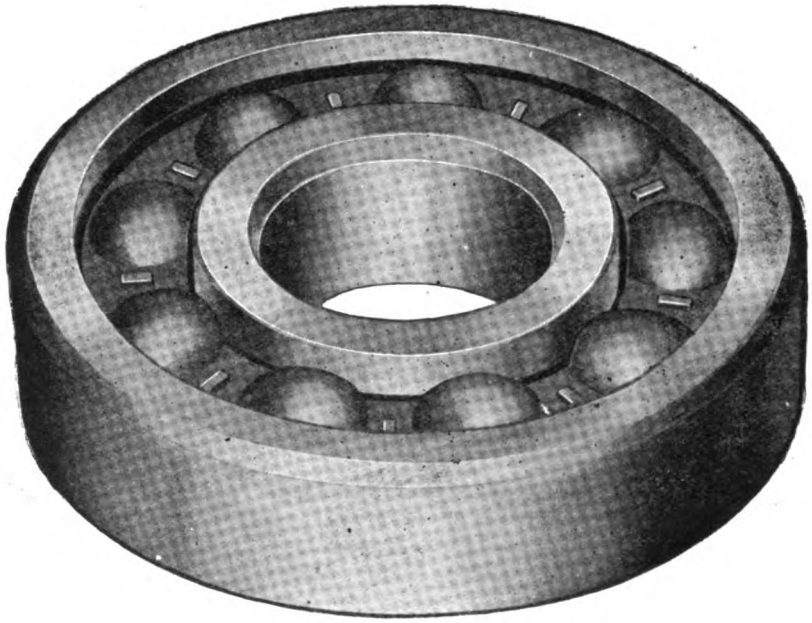
The Kellogg Manufacturing Co. lay particular emphasis on the fact that these outfits are inexpensive to operate, as well as upon the fact that the various sizes and models enable a man to select a type exactly suited to his requirements. When "free air" is such an incentive for a driver to stop at the garage where this service is extended to him, no garage man can afford to be without a power driven garage compressor. Improvements for 1916 consist of genuine babbitt bearings throughout, an oil reservoir which insures sufficient lubrication at all times, and other general refinements. Automatic electric control is a part of the equipment furnished with the larger outfits. List prices range from $70 to $240.

Large Garage Pump.

Radi-Um-Tine.

This is the name of an automobile body polish which has been brought out by the Fordham Chemical Company, 1021 East 178th Street, New York City. This polish is good not only for automobiles, but for all kinds of furniture, pianos, etc. It is also good for leather as it cleanses, softens and adds freshness to the finish, and by its use, the original texture is preserved. The same manufacturers also make a cleaning preparation called "Beats-All" which is a guaranteed tar and stain remover and is absolutely non-injurious to the enamel, paint or varnish of your car. Readers who are interested should write for prices and particulars direct to the manufacturers.

Has No Legal Authority.



We have received a letter from the Motor Specialties Company of Waltham, Mass., in which they state that a party named L. W. Sumner has lately been calling on the trade in connection with Excel Jacks and Bemus Timers in Kansas City, St. Louis and other Western cities. The Motor Specialties Company wants it distinctly understood that Mr. Sumner is not legally representing them and he has no authority to sell or solicit the specialties referred to nor to transact any business for the Motor Specialties Company or in their name. Any orders taken by Mr. Sumner will not be recognized by the Motor Specialties Co.

NEW DEPARTURE BALL BEARINGS
American Made for American Trade

THE CHOICE OF AMERICAN MANUFACTURERS who have investigated its merits ▬ ▬ ▬

One says ▬ "The use of these bearings for carrying both radial and thrust loads of the worm gear is largely responsible for the high percentage of power delivered at the road wheel contact." The use of New Departures promotes long life in whatever mechanism they are used. ▬ ▬ ▬ ▬

Don't Pay Good Money for a Private Brand!

Buy the Same Upholstery Covers from the Manufacturer and Save one big Profit

MR. DEALER, think of the best Auto Upholstery Covers of which you have any knowledge. No matter what *name* these goods may bear or what trade-mark they may be sold under, the chances are that they are *made* by Warner. For twenty-two years we were manufacturers of Buggy Accessories. For the past eight years we have been large manufacturers of Auto Accessories and have made fully 95% of all Auto Upholstery Covers shipped out of Cincinnati. The output of our factory has been marketed by exclusive distributors who sold the goods under their private brands.

This was unfair to the dealers who had to pay two profits instead of one in order to secure our product with its many features of exclusive superiority. It was unfair to the consumers who were forced to pay exorbitant prices. It was unfair to the distributors because they were building their reputation on a line of goods over which they had no permanent control. It was unfair to ourselves because it limited our business expansion to the selling capacity of the favored distributors.

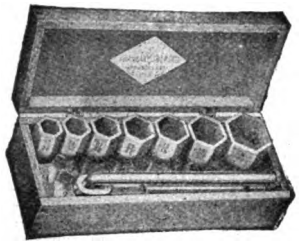
So we have refused to renew these exclusive distributors' contracts and have deliberately cut out the private brand business altogether. Hereafter we sell Warner Covers under their proper name and trade-mark.

WARNER AUTO UPHOLSTERY COVERS

FIT LIKE A GLOVE

DUST-PROOF WEAR-PROOF

Our retail list is only a trifle more than half as high as the retail lists of exclusive distributors who have been selling our goods under their own private brands. Our discounts to jobbers and retailers are fair and reasonable;—they allow for a good margin of profit and a quick turnover. Our goods will be maintained at the same high standard of quality, style, material, workmanship and fit that has built the reputation of distributors who have been selling our goods as their own product. Our stock will be kept up to date and ample for all demands. We will make rush deliveries the same day orders are received.



Here, Mr. Dealer, is your opportunity to cut out the tax that the favored distributor demands for the privilege of using his trade-mark on our goods. We do not ask you to load your shelves with a big stock of Warner Covers. But you owe it to yourself to write at once for our catalog, price-lists, trade discounts and samples of the various grades of materials of which our covers are made. Get our dealer helps and put yourself in position to command the cream of the upholstery cover business of your community by offering the best values at the lowest prices.

We have patterns for about all the leading American cars.

SACRIFICE SALE

CLOSING OUT OUR 1913 MODEL

Coupe Tops

For FORD CARS

We made and sold over 400 of these tops last season and they are now in use by satisfied customers.

We have just 50 left in stock which must be sold now.

We cannot keep them over and want to turn them into cash.

If you have a 1913 car, and want comfort in its use, mail us your order at once. We will fill all orders for these tops, while they last, for $25.00 f.o.b. Springfield.

These tops are made of hardwood frame, metal covered, glass windows, full length doors, and nicely trimmed inside. Sold last season for $100.00.

THE AUTO METAL CO.

531 Worthington St. SPRINGFIELD, MASS.

Eliminate Wear and Repair

— By Using —

TRADE MARK REGISTERED IN

NON-FLUID OIL

UNITED STATES PATENT OFFICE

Metal that rubs upon metal must be kept constantly separated, else friction results. Friction robs your car of free motion, wastes energy developed by your engine and destroys vital parts. Only **perfect lubrication** can overcome these troubles. Only **perfect lubrication** stops frictional wear on gears and bearing. Only **perfect lubrication** can obviate costly repair bills.

No lubricant of any kind that has ever been produced will do so much work in reducing friction as NON-FLUID OIL. Broad claim this—but a trial will prove it. NON-FLUID OIL will stand extremes of temperature without changing in consistency or without losing one atom of its surpassing lubricating quality. There is no gumming up, no leaking out, no clogged or dry bearings when you use NON-FLUID OIL. It is the **only** lubricant which really fills the teeth of transmission and differential gears, and insures quiet, smooth operation, absence of noise and shock when changing speed, and efficient serviceability until the old age of the car. It is the most economical because it lasts 3 to 4 times longer than LIQUID-oils, or greases.

Get a Can Today and Prove It

Reduced Prices. Ask your dealer. The original NON-FLUID OIL is identified by orange-colored cans bearing the above sprocket-wheel trade mark. Avoid substitutes.

New York & New Jersey Lubricant Co., 165 Broadway, New York
1430 Michigan Ave., Chicago

Differential Improvement.

The M. & S. Differential is a new construction which prevents the spinning of a drive wheel in soft places. Under such circumstances, a locking of the differential takes place practically automatically, without the need of separate action on the part of the driver. It naturally follows that, as this action is automatic, it is instantaneous and comes into play the moment the disturbing road conditions present themselves, so that a car does not "dig itself in" and find itself in difficulties from this cause, but is able to make the best of the drier road surface under the other wheel. When road resistance is sufficient to give adhesion to each driving wheel, both wheels are equally driven, the crown wheels to which they are attached being carried bodily round by the worms in which they are in engagement, just as, with an ordinary differential, they are carried round by the pinions. But when road resistance upon one wheel is reduced to a point at which it loses adhesion, and would, with the ordinary differential start spinning, nothing of this kind happens, because the angle of the worms is such that, whilst the crown wheels can drive the worms, the worms cannot drive the crown wheels, and, as a consequence, the differential is locked so far as any movement of the wheel in relation to the differential is concerned. The axle becomes for all practical purposes a solid one, and all the drive is taken up by the wheel which is for the moment supported on firm ground and can take advantage of its grip. It is claimed that this new device not only meets the wheel-spinning difficulty entirely, but at the same time prevents skidding, or sideslip on greasy roads. It is made by the M. & S. Gear Company, Detroit, Mich.

FORD DETACHABLE RIMS (5)—Oiled or painted wood wheels, per set, $13; 30x3½ front wheels, $4. B. J. Potter, Okemos, Mich.

Detroit Batteries.

The Detroit Battery Company of Detroit, Mich., have made a successful move in their campaign to bring the merits of Detroit Batteries home to automobile owners by making a 50 per cent. reduction in their list prices. Detroit Batteries are the result of over 35 years of experience in battery building. The men in the organization were associated with the inventor and producer of the first successful commercial storage battery. Detroit Battery Cells are tested with 30,000 volts. The grids in these batteries are cast in the plant owned by the manufacturers. The oxides are blended as only life long experience can blend. Every carboy of acid is thoroughly tested. Every gallon of water used is distilled by the manufacturers. The battery boxes used are of the finest woods. These batteries are made for every type of car and they are also the standard equipment on many kinds of American made cars. The Detroit Battery Company have a special dealers' proposition which they wish to submit to any of our readers who may be interested. Write for full particulars to the Detroit Battery Co., Detroit, Mich.

Now the Light Eight.

The Lightweight eight cylinder car, successor to the light six, has made its appearance in the Apperson Light Eight. There have been small eights which are necessarily light but none which is analogous as a whole to the forty and fifty horsepower six. The Apperson Light Eight tips the beam at less than 3,100 pounds, fully equipped, with gasoline and oil, ready for the road, and its specifications show it to be in the luxury class as far as size is concerned. One hundred and twenty-eight inches is the span from front to rear wheel. The greatest saving in weight is found in the motor and according to Apperson officials its lightness is due to simplicity and costly materials.

Double-Focus Headlight.

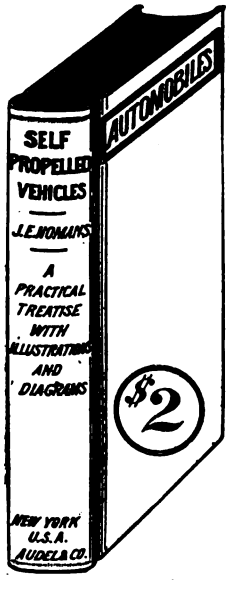
A new type of headlight in which the dimming problem is solved by means of a double-focus reflector and two lamps, both of which are in focus, is now on the market. The larger of the two lamps is intended for use only in country driving. The light from this lamp is directed horizontally and gives effective illumination of the road for a distance of three hundred feet or more, according to the candle-power of the lamp used. The smaller lamp gives a light of somewhat less strength that is directed downward at such an angle that the road is well illuminated immediately in front of the car for a distance of from 75 to 100 feet. As no light whatever is projected above the level of the lamp itself, all glare is eliminated. The larger lamps need never be turned on in the city, as the smaller ones give ample light for all conditions, except for fast driving on country roads. It is said that the greatest advantage of this new type of headlight is, that in passing another vehicle while driving in the country at night, one can "dim" his lights to the extent of positively eliminating all glare from his headlights, and yet keep the road in front of his car brilliantly lighted for a sufficient distance for safe and comfortable driving. This headlight is being placed on the market by W. M. S. Miller, 3508 Cedar Street, Milwaukee, Wis.

A Good Solder.

Hess & Son, Philadelphia, Pa., make a large line of soldering devices and products. Those who have this work to do may be sure that this firm will supply them with anything they need. They make Tinol, which is a non-corrosive solder, and has the advantage of not requiring anything else whatever to make a complete job of mending. It is clean and the joint does not have to be prepared as with ordinary solder. It should be in every automobile shop and the Tinol automobile soldering outfits are simple and of low cost. This outfit is unusually good for soldering wire cables and for locking nuts and screws by solder.

New Storage Battery Plant for Prest-O-Lite.

The Prest-O-Lite Co., of Indianapolis, have in process of erection a large addition to their present plant, this new portion to be devoted to the manufacture of storage batteries. The building will give the Prest-O-Lite people an additional floor space of 45,000 square feet, and represents an addition of one-third their present floor space. Work is being pushed vigorously on the new storage battery plant, and it is expected it will be ready for operation by December 1, 1915, with a capacity of 400 batteries per day.



Harvey Boltless Auto Springs.

The Harvey Spring Company, 849 17th Street, Racine, Wis., in order to overcome the variations always found in hand-made auto springs, have invented and patented an automatic machine for forming and tempering spring leaves. This machine does the work so accurately and uniformly that they are able to guarantee Harvey Auto Springs against all defects. These springs are made without a hole at the center, a small depression or bead prevents the plates from shifting and all the strength is preserved at the center. There are no weak spots. These springs are strong, durable and easy-riding, and the manufacturers state that they mean freedom from spring repairs, and are a source of constant satisfaction to users. Dealers, jobbers and garage men will find the Harvey Spring Book very valuable in ordering replacements. It contains a complete list of springs for standard cars, gives sizes, weights, measurements and other valuable information that has never been published before, and is of great assistance in ordering. A copy will be mailed absolutely free, if you will take the trouble to ask for it.

It Cost $1,400 to Hurry This Contractor.

What is believed to be a record for a rapid and thorough building construction has just been made in this city at the plant of The Hydraulic Pressed Steel Company. When, on June 28th, the contract was let for the erection of a building 360x80 feet to be made of steel, concrete and glass and to be finished in eight weeks, it seemed like an impossible undertaking. The contractor naturally objected to the penalty of $100 per day for each additional day required. The contract was closed on that basis however, with the usual clause of $100 per day bonus for each day less than the required time. Nobody supposed it would be possible to erect the building in less than fifty-six days, and therefore, little thought was given to the bonus part of the contract.

The contractor, however, broke all records, and succeeded in completing the work in forty-two days, thereby earning a bonus of $1,400. Every modern factory convenience is to be found in this building, from the electric cranes overhead to the pipe tunnels underground. When the heavy hydraulic machinery is installed this building will be the largest and most complete in the world, devoted exclusively to the manufacture of pressed steel automobile frames.

Auto. Educator.

EVERY OWNER, OPERATOR AND INTENDING PURCHASER SHOULD HAVE THIS WORK.

This book was written to meet the need for a simple but comprehensive treatise of motor car construction and care—a book that is not only a necessity to the motor car owner, but also useful to the skilled engineer and mechanic.

Being clear and concise in its treatment of the subject, and is comprehensible to the most inexperienced man. At the same time it is so thorough and detailed that the expert will learn much from its pages.

The treatise on gasoline cannot fail to prove valuable to anyone interested in explosive motors, which are daily coming to the front as the readiest and most convenient source of power. ¶The price of this popular edition is $2.00, and as an insurance against accidents, caused by ignorance of the principles of operation—of which there are a lamentable number recorded every day—no one interested in the subject can afford to do without a copy of this timely volume.

Ford Car Pumps.

The Hert Mfg. Company of Indianapolis, Ind., make what they call "Purair" pumps for Ford cars, which take the terror out of tire troubles and fill a long felt need. They are simple and pay for themselves in a short time in the saving they effect on tires alone. The pumps are equipped with an automatic relief valve which is set for the proper pressure and which sounds a warning signal when the tires reach this pressure. In fact when they are pumped to that point, no more air can enter the tire. These pumps are low in cost, are guaranteed to last and the purchase money will be refunded without quibble if they do not give satisfaction.

An Engine Trouble Detector.

The Lazarus Manufacturing Company, 744 Euclid Ave., Cleveland, O., has brought out an engine trouble detector which is extremely convenient. With it you can locate and determine engine troubles by the dash without raising the hood. It is especially reliable in case of faulty ignition, loose connections and lack of compression. The device is not complicated and can be easily installed. This is one of the very best of the "Lazco" products, which include vulcanizers, lubricators, fire extinguishers and vacuum cleaners.

Marvel-Mist.

The Marvel-Mist Manufacturing Co., of 48 Greenpoint Avenue, Brooklyn, N. Y., have sent out a corps of salesmen who are cleaning up the Western territory with their polish, and a little later the result will be seen in the cleaning up of automobiles used there. This polish has now become thoroughly established as something of superior character, and it is extremely easily applied.

The Nifty Chain Tool.

Will A. Sapp, Elgin, Neb., is manufacturing several devices useful to the automobile owner and repairman and among them is a tool for putting on mud chains. It does this rather untidy job quickly and without soiling the hands. The cost is trifling. Car owners will find it convenient to have one. This firm also makes a foot accelerator for Ford cars, which is simple and efficient. For further particulars address as above.

Edison and the Electric Incandescent Lamp.

Edison Day, October 21, commemorated the thirty-sixth anniversary of the invention of the electric incandescent lamp and honors its master inventor, Thomas A. Edison. Mr. Edison has emphasized the value of continuous research work and given us a vision of the future in the science and art of electric lighting. "No invention is perfect," he says, "and the incandescent lamp is not an exception. Light without heat is the ideal, and that is still far off. The electric incandescent lamp of to-day is the cheapest form of filament that has ever been produced, but some day it will be cheaper and colder than it is. There is a good deal of truth in the saying that the firefly is the ideal. It is, so far as coldness goes. But its color is against it. You couldn't use a thousand candle firefly to match colors, and you wouldn't want the insect to light up a street, because his light would be a hideous greenish yellow. But some day we will get reasonably

Mosler
Spit Fire
Plugs
ARE THE BEST
A.R.MOSLER & CO.
P.O.BOX "M"
MT.VERNON. N.Y.

near the firefly for efficiency without copying his disagreeable color. The task needs much investigation, much research of the kind we did in 1879. The research that we began then is still going on, and it always will go on. Somehow, each new discovery opens up the way to another."

Franklin Prosperity.

Wages of about 1,200 employes of the H. H. Franklin Mfg. Co., Syracuse, N. Y., have been increased by two cents per hour. This means an addition of $57,000 to the yearly payroll, and was made voluntarily. The company states that the installation of an efficiency system has increased the profits of the enterprise and that it was thought just that the men should share in the increase.

Dayton Radiator Fix.

This is a new radiator cement which is manufactured by the Wearwell Rubber Company, 1033 West Third Street, Dayton, Ohio. The manufacturers guarantee that this cement will stop a radiator leak in three minutes or money back. Nine automobiles out of ten, it is said, have trouble with leaking radiators and if yours has not leaked yet, it may before long. A package of Dayton Radiator Fix may be a very handy thing for you to carry in your kit. It sells for only 50 cents per package and there is enough radiator cement in one package to mend all the leaks you are likely to have for a long time to come. Readers who are interested are urged to send their orders direct to the manufacturers or else write for testimonials and full particulars. If you will send 50 cents to-day for a package of this cement and it is not found entirely satisfactory, the Wearwell Rubber Company is willing to refund your money at any time. This is a good dealers proposition and agents are wanted for it all over the country.

New Factory for Hyatt.

The increased business of the Hyatt Roller Bearing Co. has made it necessary to greatly enlarge their plant at Detroit. The factories are located at Detroit, but an immense warehouse and a large office building are in course of erection at Cass Avenue and West Grand Boulevard, Detroit. The company has a frontage of 225 feet on the Michigan Central Railroad, and the new warehouse will be of modern construction, two stories high and having 20,000 square feet of floor space. The business of this company in bearings for automobiles has grown to such an extent that a car load of bearings is delivered daily in Detroit, and this rate of shipment will be maintained throughout the year, the new warehouse being the base of distribution. and there will be facilities for keeping on hand at all times a supply of all the popular sizes of Hyatt Bearings which can be delivered immediately to the large automobile factories in Detroit. H. R. White who has been connected with the automobile division of the Hyatt Company for some time has been named Traffic Manager, and will have charge of the extensive shipping arrangements.

MR. DEALER:

Here are two of the biggest Money Makers of the year. Our dealers are "Cleaning Up" on the 1916 **MECCA 30** *at $695, and the* **NEW TWOMBLY** *at $195.*

These cars are easily worth twice what we are selling them for and the public is quick in recognizing this. Both the **MECCA** *and the* **TWOMBLY** *sell on sight.*

We have some open territory in which thousands of these cars can be sold. Apply at once for details of our excellent dealer proposition.

HARVEY BOLTLESS AUTO SPRINGS ARE GUARANTEED FROM END TO END

In order to overcome the variations always found in Hand-Made Auto Springs we invented and patented an Automatic Machine for forming and tempering spring leaves. This machine does the work so accurately and uniformly that we are able to guarantee Harvey Auto Springs against all defects.

Harvey Springs are made without a hole at the center and a small depression or bead prevents the plates from shifting and all the strength is preserved at the center. There are no weak spots.

Harvey Springs are Strong, Durable and Easy-riding. They mean freedom from Spring repairs and are a source of constant satisfaction to users.

Jobbers, Dealers, Garagemen

will find the Harvey Spring Book very valuable in ordering replacements. It contains a complete list of springs for standard cars, gives sizes, weights, measurements and other valuable information that has never been published before and is of great assistance in ordering. Copy mailed free. **Write for yours today.**

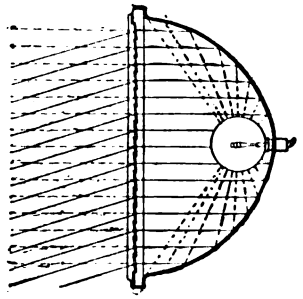
The Harvey Spring Company, 849 17th Street, Racine, Wis.

Keep Your Car Bright

Every motorist should take pride in the appearance of his car. The car should not only be washed thoroughly whenever necessary, but care should be taken to preserve the luster of the varnish. For this purpose, experienced drivers highly recommend Johnson's Prepared Wax, which may be used to advantage on bodies, hoods and fenders. It will preserve the varnish and protect it from the weather as this wax sheds water and does not gather dust. There are thousands of delighted users of this preparation all over the country, and it is prepared by S. C. Johnson & Son, of Racine, Wis. To introduce it among our readers, the manufacturers offer to send a generous sample, enough for polishing a large car, on receipt of ten cents in stamps and the coupon which is attached to their advertisement in this magazine. We feel sure that a large number of our readers will want to take advantage of this generous offer.

Coupe Tops for Ford Cars.

Many of our readers are owners of the 1913 Model Ford cars, and as the winter season is now coming on, a great number of these owners are likely to be interested in special Coupe tops. The Auto Metal Company, 531 Worthington Street, Springfield, Mass., have on hand about 50 Coupe tops for 1913 Model Ford cars, which sold last season for $100 each, and they offer to close these tops out while they last, for only $25.00 each, F.O.B. Springfield. Over 400 of these tops were sold last season at the full price of $100, and they are now in use by satisfied customers all over the country. These tops are made of hard-wood frame, metal covered, with glass windows, full length doors, and nicely trimmed inside. For only $25.00, one of these tops will enable you to change your summer car into a closed winter vehicle, and we predict that the Auto Metal Company will sell out the small stock of these tops which they have on hand in a very short time.



Kills the Glare, Not the Light.

A very large number of automobile accidents have been caused by glaring headlights, and as a consequence many cities through the country are passing ordinances against the use of these glaring lights. The Opalite Deflector, a new invention, absolutely kills the glare of the headlight, but it does not kill the light. It merely turns dazzling, dangerous light into soft, luminous beams, and

Opalite Deflector.

it is claimed that the penetrating power of the light is just as strong but without the objectionable glare. The Opalite Deflector fits the rim of the lamp the same as glasses fit the human eye, and the device is made to fit all makes and sizes of automobile lamps. Thousands

How the Light is Deflected.

of drivers who are using this invention say it exactly meets the requirements, and many of our readers will doubtless be glad to investigate. The illustrations give a good idea of the appearance of the Deflector as applied to the lamp, and also show how the rays of light are deflected. The Opalite Deflectors only cost $2 per pair, making them easily within the reach of any car owner. All orders and inquiries should be addressed to the M. & K. Auto Sundries Co., 1777 Broadway, New York City.

Pistons for Ford Cars.

Pistons of good quality made of soft grey iron and accurately machined are manufactured by Depuy Bros., Canterbury, N. H. These pistons are exactly of the correct weight—3 lb. and 9 oz.—and they are shipped complete with rings, pin and bushings. A complete assortment of sizes is kept on hand for immediate shipment including standard size, or .005 in., .015 in. or .030 in. oversize. By a regrettable error in our September issue, we referred to Depuy Bros. as manufacturers of piston rings, which was absolutely incorrect. This firm is ready to supply our readers with pistons, and the price for each piston, cash with order, is only $1. This ought to be interesting to a great many Ford repairmen, and all orders will be filled with the utmost promptness.

A Two-Step Extension Pedal.

This is a novel device which has been recently put on the market by the Van Derbeck-Sayers-Murdock Co, of 1834 Broadway, New York City. Cars are frequently driven by people of varying heights and what is convenient for one driver in the way of pedal position may be too high or low for another driver. With this device there are two heights of pedal available at the same time and all the time, and for family use this is an improvement which will be greatly appreciated. The adjustment of the extension or upper pedal is provided for in two clutch joints, by which the amount of the lift above the main pedal and the degree of tilt of the extension pedal may be regulated to suit each driver. The pedal is attached by means of a screw clamp, it does not deface the main pedal and there is plenty of room between the two pedals for the lower pedal to be used by longer-legged persons. The extension pedal is priced at $5 per pair and it is neatly made of steel, nickel plated.

STOP THAT LEAK

You are using too much oil!
You are wasting gasoline!
You are not getting enough power!
DON'T THE UP-KEEP GIVE YOU THE BLUES?

Trade Mark

Patent Applied For

There was a time when water pumps at the City water stations used a fabric or leather packing; not so today. A copper jacket is put in the cylinders. **Large grooves** are cut in the pistons, the volumes of water in the grooves form a packing, small particles of water cannot pass the volumes of water in the grooves. Thus making a perfect packing of water against water. Just so with "NO-LEAK-O" Rings. The volumes of oil in the grooves act as a packing against the oil being drawn or forced up into the firing chamber. "NO-LEAK-O" piston rings have grooves which CONTROL THE OIL, giving perfect lubrication without waste. No smoke. No carbon. No oily spark plugs. No grinding of valves. We absolutely guarantee each ring for QUALITY, ACCURACY and SATISFACTORY service. ONE PIECE, LOW COST, HIGH EFFICIENCY. Carbon eliminated by controlling the oil. ***Write at once for complete particulars.***

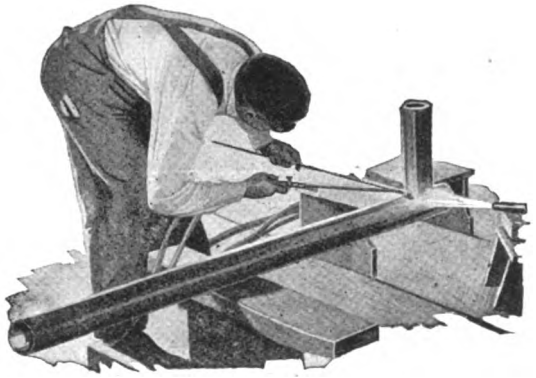
Oxy-Acetylene Welding and Cutting

Prest-O-Lite PROCESS

Did for only 75c what would have cost $7.50

Every maker of automobile parts and every garage and repair shop, should know the boundless possibilities of economy through uniting metal parts by oxy-acetylene welding instead of by older methods.

Practically all the automobile factories use this process in the manufacture of cars.



One railroad shop saved $5,000.00 in a single month on repair work alone.

You can make proportionate savings in your shop. Nearly all motor car makers use oxy-acetylene welding in various manufacturing operations, because they secure a better product, and smaller cost.

Live garages are cutting repair costs and making friends through the saving of time and money for patrons.

In your factory, in your shop, there is a profitable place for this remarkable, low-cost process. If you cannot find that place, give us a chance to find it.

Necessary equipment is not expensive. We furnish high-grade apparatus for $60; acetylene service extra. Adaptable for oxy-acetylene cutting with the addition of special cutting apparatus.

Welding branch into 3-in double extra heavy pipe for hydraulic service, 3,900 lbs. to the sq. in., eliminating "T" fitting with threaded joints and consequent possibility of leakage. Welding cost, 75 cents "T" fitting cost $7.50.

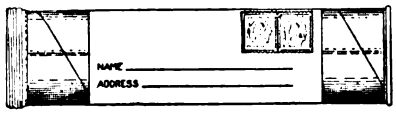
Large Profits in Job Welding

Doing oxy-acetylene welding for others is a splendid business in a large and growing field. No enterprising man can afford to neglect this opportunity for good legitimate profit.

Prest-O-Lite Acetylene Service

Furnishes the highest grade of Dissolved Acetylene (ready-made carbide gas) in portable cylinders. Used as conveniently as cylinders of oxygen. Saves large initial outlay and heavy depreciation of making crude acetylene in carbide generators. Perfectly dried, cleaned and purified—makes better welds and is cheaper to use.

Send for Information—NOW



Write today for valuable engineering data on oxy-acetylene welding and cutting—how others have saved time and money in repair and manufacturing operations. Write about it. Thoroughly illustrated book free on request.

Complete Repair Outfit

Every GARAGE, PUBLIC or PRIVATE, needs this BIG, STRONG, EVERLASTING COMBINATION OF TOOLS which we call the

STEWART HANDY WORKER

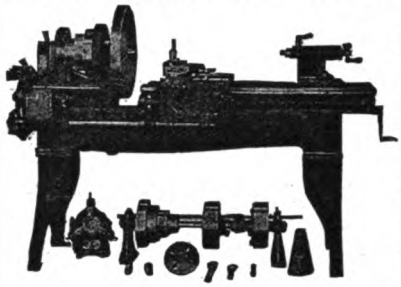
Weighs Boxed 90 Pounds

Price Complete Only $12.50

If you bought all the tools you get with it, of the same high quality, strength and durability, and the equipment to operate them, they would cost you at least $25 at wholesale price.

Each one a tool you can use every day to save time and money. A complete, compact workshop that you can attach to a table or bench anywhere about the garage and make it pay you big profits. It will enable you to quickly and easily do any ordinary repair job.

NOTE WHAT IT INCLUDES



A strong, practical anvil; powerful vise, up to 4½ inches, width of jaw 4 inches; a sure-grip steel pipe vise, takes up to 1½ inch pipe; a Corundum grinding wheel, 5 inches x 1 inch; a two-speed drill press with 2 drills; a metal cutting wedge and driving mechanism of three speeds—direct, 4 to 1 and 16 to 1—easily regulated by changing the handle grip. It operates grinding wheel, small circular saw, buffing wheel and many other similar tools. With the Stewart "Handy Worker" you can do your own automobile repairing, etc., blacksmith work, home repairing, make plumbing repairs, keep knives and other cutting tools sharp and in good working trim.

Send for one of these great combined outfits today with the understanding that if you don't like it in every way you can ship it back and we will return every cent you paid out. Of all the thousands shipped, not one customer has made a single complaint. It pleases every customer, but our standing offer to return every cent paid out holds good to each purchaser.

SEND ONLY $2.00 WITH YOUR ORDER and pay the balance when it arrives. ORDER TODAY OR WRITE FOR BOOKLET.

MANLEY COMPRESSORS DELIVER THE GOODS

Save 50 per cent of your electric power on your compressor by using a Manley Type C Compound Compressor. Needs only 50 per cent as much power to compress the same quantity of air. Effecting a big reduction on the wear and tear on the bearings and parts, resulting in a much longer life, which means less repairs and replacements.

If you prefer a single stage compressor, you will be impressed with the sturdy construction of our Type D Compressor, which is designed to meet the demand for a thoroughly reliable long wearing compressor **with adjustable bearings throughout** which will stand up to its work without trouble.

These facts account for the universal satisfaction they are giving wherever installed. Nine sizes to choose from.

Steer Warms

Keep Your Hands Warm While Driving

Drive in comfort. Steer Warms consist of two neat leather covered grips, one for each hand, which lace on the steering wheel at any place convenient for driving. They operate on the same principle as an electric heating pad. They are simple, efficient, and cost little to maintain.

Make Driving Safer—Steer Warms keep your fingers limber so you can grip the wheel tight, making driving safe on slippery streets.

Also Preserve the Health—When you keep your hands warm, you keep your body warm and you do not catch cold. Steer Warms make for comfort and health.

Easy to Install—Steer Warms are easy to attach. They can be put on in ten minutes. No bolts and screws, or holes to bore. Lace on, wire up, that's all.

GUARANTEE—Steer warms are guaranteed for five years against burn out. They are guaranteed to do all we claim or money refunded. If your dealer hasn't them we will send direct. (When ordering state make of car and voltage of battery. If Ford car, whether 1914 or 1915 model.)

PRICE

For FORD CARS $5.00 In Canada $7.25
For Other Makes 7.50 " " $11.00

—DEALERS—

These self-selling accessories are in big demand. They are being advertised extensively and they appeal to the popular imagination.

You Make a Good Profit

Because of the demand for Steer Warms and Ieco Manifold Plugs, the ease with which they are sold, and the fact that you do not have to carry a large stock, makes them profitable items for you to handle. ***Write for full information to-day.***

Ieco Electric Manifold Plug

STARTS CAR QUICK IN ZERO WEATHER

This wonderful plug puts a hot vaporized mixture into the cylinders causing the engine to start at once. It will start the engine on the first or second turn anywhere. When self-starter is used it saves the battery. The plug is inexpensive to maintain, easy to install, simple and compact, and guaranteed against burn out within two years. If not as claimed money refunded. At all dealers. (When ordering, specify voltage of battery—Ford cars require six dry cells.)

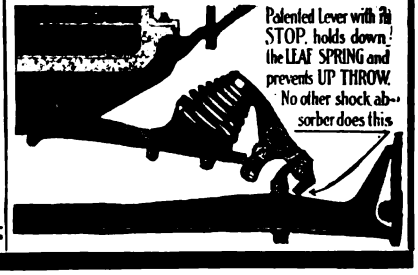
PRICE $5.00 In Canada $7.25

Saves 25% Gasoline!

When used as an auxiliary air plug, the engine uses more air and less gasoline. Saves 25% on gasoline bills. Plug will pay for itself in three months.

HASSLER

$15 FOR A SET OF FOUR



PRESTIGE

Means More Sales

DEALERS that are selling Hassler Shock Absorbers for Ford cars, are selling a shock absorber plus the prestige that 3 years of successful use on 50,000 Fords gives it, plus the rigid guarantee of a pioneer concern that depends upon **one** product for its success. These dealers are "cashing in," in a big way. The Standard of Perfection that the name Hassler stands for, makes selling easy. You can sell the Hassler.

Write for our selling plan. We want to send you a trial set. Not sold through jobbers. We protect you.

Robert H. Hassler,
Incorporated
Indianapolis, - Indiana

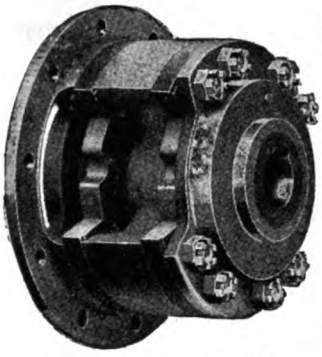
INLAND

1 PIECE PISTON RING

A perfect one-piece Piston Ring

that has all the virtues of eccentric, concentric and more-than-one-piece construction; and none of their disadvantages.

A continuous ring cut spirally for half its circumference; heat-treated so that the free ends hug tightly together; the result is an absolutely *gas-tight* ring that uncoils in expanding, insuring uniform pressure and perfect contact with the cylinder walls.



The strongest gas-tight ring on the market, because of its simple one-piece construction, and, for the same reason, it costs less to buy, and less to install, for it is easier to put on and will not break in handling. Made of close grain cast iron.

Absolutely guaranteed; money refunded on any ring that fails to give perfect satisfaction after 90 days' trial.

Full description in free booklet.
Dealers and jobbers should write for interesting prices.

The Bailey Gearless Differential

Thousands of Sales This Fall to Cold-Weather Drivers

Thousands of Ford owners will buy the Bailey Gearless Differential this Fall in preparation for the slippery, sleety, icy streets and roads of Winter.

For the Gearless Differential, absolutely reducing skidding and sidesway to the minimum, is the best safety-insurance the Ford owner can have.

The positive drive to both rear wheels gives all the advantages of a solid axle in straightway driving. And in ruts or mud, sand or snow, power is delivered only to the wheel having traction. Bailey-equipped cars have made some wonderful pulling records on bad roads.

Now is the Time for Dealers—Money-Back, No-risk Proposition

Write today for particulars of our sales plan. It involves no risk on your part, and it gives you the closest co-operation you have ever had on an accessory.

Hundreds of dealers are making good profits out of it now.

"Bridgeport" BRASS TRADE CO. MARK

A Bridgeport Pump For Any Size Tire

The merit of a tire pump may be determined by the amount of effort that pump requires to inflate a tire—the larger the tire, the more apparent the difference in pumps will become. From Ford size tires on up, they all look alike to the man who carries a Bridgeport Pump.

We know we make and sell by far the greatest number of Automobile Tire Hand Pumps—if not more than all other makes combined. We believe that the size of our business is due solely to the superiority of

BRIDGEPORT PUMPS

in materials, in workmanship, in efficiency and in ease of operation. And just because a Bridgeport Pump will give infinitely better service than any other—and that kind of service indefinitely—be sure you get a BRIDGEPORT.

Bridgeport Brass Company

SMITH'S NON-SKID CANVAS TREAD TIRE construction guaranteed for 5000 miles but average is 10,000 miles. Two strips of rubberized canvas projecting from the inside of the tread to the outside, makes this tread non-skid all the way through, and also acts as a radiator, preventing the tread from heating, peeling off. Also prevents stone bruises, punctures and blow-outs. It draws easier than tires with knobs on the tread and saves 25% in gasoline. **Free booklet describing other important features and agent's proposition.**

CATALOGUE ON APPLICATION

Pressure Proof Piston Rings

stop oil troubles because they take up side wear in piston groove by means of the spring expander acting on the bevel on the under side of the ring. This feature appears in no other piston ring.

They are made of soft cast iron, no steel or composition to score cylinders.

Ever see a piston ring that would give perfect service after being broken? The Pressure Proof is the only ring that will do this. Let us tell you how.

The Pressure Proof Ring will give longer service and higher efficiency than any other ring made, regardless of price or construction.

Install a set of these rings at the next opportunity. We guarantee that you will make a discovery about piston rings.

Write now for particulars and dealers' proposition.

NEW YORK LONDON CHICAGO

When the Car Smokes

It's a Sure Sign of Leaking Piston Rings

Too much lubricating oil is being admitted to the combustion chamber where it burns and leaves a carbon deposit. The smoke you see is carbon too. It simply means needless waste. But the carbon that remains inside is an abrasive, and soon wears the bearings of the whole engine.

BURD High Compression Rings

Render such action impossible. The "guarded opening" prevents an excess of oil from being drawn into the combustion chamber. It can't get by. Let us tell you other "money-in-the-bank" reasons for BURD RINGS.

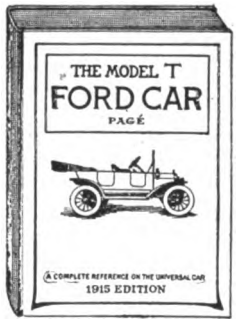
TEACHES YOU HOW TO REPAIR, ADJUST AND DIAGNOSE TROUBLES
Also covers Salesmanship

Every subject is fully treated; **ENGINES**, from one to twelve cylinder. **CARBURETION**—beginning at the simplest form, to the adjustment of all leading makes. **IGNITION**—from low tension coils to the latest battery and coil and magneto systems. **Care of a Car**; Operating a Car; Lubrication; Building and Equipping a Garage, for home or pleasure; Self-Starters—in fact, every subject is fully covered.

All electric starting and generating systems up-to-date. **The late fourth** edition of the Encyclopedia contains 700 pages with 1750 illustrations. Trucks, Tractors and a complete **FORD INSTRUCTION** added. Also a simplified instruction on 6, 8 and 12 cylinder engines.



VALUE OF THIS INSTRUCTOR TO YOU

WE CLAIM that with careful study of this instructor, it will enable you to become: (1) **AN ENGINE EXPERT** capable of diagnosing ignition, carburetion, valve timing, cooling troubles, and remedying them. (2) **A DIAGNOSIST** who from knowing the principle and construction of all subjects, can instantly tell the cause of any trouble and apply the remedy. (3) **A RUNNING GEAR EXPERT** capable of diagnosing and remedying such troubles as differential, transmission, axles, brakes, steering wheels and axle troubles. (4) **AN AUTO MECHANICIAN** who can adjust and remedy all the troubles after diagnosing. The subject of repairing in this Instructor is complete in every respect.

A NEW, COMPLETE BOOK
FOR EVERY FORD OWNER, DEALER, SALESMAN and REPAIRMAN

THE MODEL T FORD CAR
ITS CONSTRUCTION, OPERATION AND REPAIR

By VICTOR W. PAGÉ

Member of the Society of Automobile Engineers,
Author of "The Modern Gasoline Automobile," etc.

300 (5x7) Pages
Over 100 Specially Made Engravings
AND TWO LARGE FOLDING PLATES

Price $1.00

This is the MOST COMPLETE and PRACTICAL instruction book ever published on the FORD CAR. Illustrated by specially made drawings and photographs. All parts of the Ford Model T Car are described and illustrated, in a comprehensive manner—nothing is left for the reader to guess at. The construction is fully treated and OPERATING PRINCIPLES MADE CLEAR TO EVERYONE. Complete instructions for *driving* and *repairing* are given. Every detail is treated in a non-technical yet thorough manner.

LET US TELL YOU
why you should use

NATHAN

RADIATOR and HOOD COVERS

They are made of the best materials and fit perfectly.
The workmanship can't be beat.
The unquestionably low price speaks for itself.
They do the work and have stood the merciless test of comparison.
They have convinced the keenest buyer of their superiority over all others.
They keep the cold out and the heat in, and prevent water from going between the hood hinges on to the plugs. Makes car start 100 per cent better in cold weather and saves gasoline. Has all necessary fasteners.

Don't accept cheap substitutes. Every genuine Nathan Radiator and Hood Cover bears our trade-mark. Look for it. Reliable dealers have them. If your dealer can't supply you, we will forward postpaid on receipt of price.

Write for full description and price. We will refer you to nearest dealer handling the Nathan Line.

ALSO FULL LINE OF

Stormy Weather Necessities — Lock Top Tire Covers — Seat Covers
Steering Joint Protectors — Top Hood Covers — Door Pockets, etc.

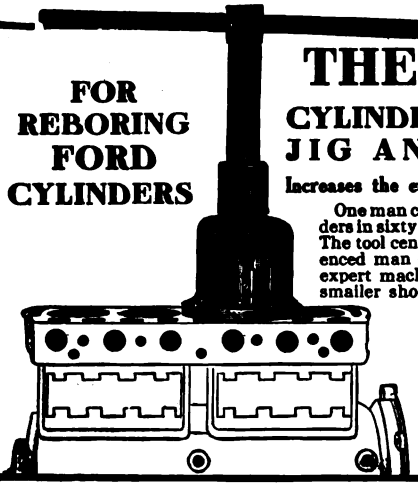
HEISER'S IMPROVED CYLINDER REBORING TOOL FOR FORD ENGINES

REPAIRMAN

There has been a period in your life that you were unable to tell a valve from a spark plug, a magneto from a carburetor, or a cylinder from a piston; some one had to tell you what these parts were and their function. The troubles arising from these and other parts of a car, you have mastered, but you are still at sea if you do not understand and are not prepared to rebore and fit oversize pistons, for this is the most important repair that can be given a worn engine.



The HEISER IMPROVED CYLINDER REBORING TOOL for Ford Engines, makes a good shop out of a poor one and a better shop out a good one, but best of all, it gives the owner service. The end of this season will see one million Fords on the highways; this means many million dollars will be spent on reboring and fitting oversize pistons.

The early bird catches the worm. We furnish oversize pistons to fit the rebored cylinder, $1.50 each, Complete.

Write for further particulars about this wonderful tool.

HEISER SPECIAL TOOL CO., (Dept. A) **KINGSTON, MO.**

FOR REBORING FORD CYLINDERS

THE DAVIS
CYLINDER REBORING JIG AND REAMER

Increases the earning power of your shop

One man can rebore a set of four cylinders in sixty minutes with this machine. The tool centers itself, and an inexperienced man can do as good a job as an expert machinist. With this tool the smaller shops and garages can rebore cylinders and guarantee the work to be as good as the larger dealers with their expensive machinery. Makes the motor better than new. Write for price and full particulars.

DO YOU WANT A MOTOR CLOCK

For your car, and a good one? The clock illustrated in this connection is manufactured by one of the most reliable clock companies in the country and is warranted in every respect. It is not liable to get out of order. It has interchangeable parts. It is the product of skilled labor combined with the most improved Waltham Automatic Machines. This clock is 3⅜ inches high, and has a Porcelain dial 2½ inches in diameter. It has a one day movement with second hand. It can be furnished in burnished brass or nickel plated whichever is preferred. The arrangement we have made enables us to furnish **one of these clocks and a subscription to the Automobile Dealer and Repairer for a year** to all residents of the United States and its territories for the precise price the clock retails for, namely, **$2.50.** If an eight day clock is preferred send 50 cents extra or $3.00. Canadian subscribers should add 50 cents extra to cover the extra postage required on the **Automobile Dealer and Repairer.** This clock cannot be sent to foreign countries. The clock can safely be sent by mail and will be forwarded postage prepaid to any part of the country. Remittances can be made in any convenient way. Address

MOTOR VEHICLE PUBLISHING CO.
71-73 Murray Street, - - - - New York, N. Y.

Every Repair Shop or Garage SHOULD HAVE A CLOCK.

We have recently made very favorable arrangements with one of the largest clock companies in this country by which we are enabled to offer to our readers in the United States or its territories a **Regulator Eight Day Calendar Clock** 38½ inches high, with a 12 inch dial, finished in **Oak** or **hand-rubbed Mahogany,** with a subscription to the **Automobile Dealer and Repairer** for one year, at the very low rate of **$3.90.** This clock cannot be sent to any foreign country except Canada, and Canadian subscribers must send **50 cents** more to cover extra postage on the paper. ●

Every repair shop, garage or dealer's office should have one of these clocks. It will give you the time of day correctly and the day of the month.

The engraving shown gives the correct appearance of this clock.

This offer is good for either old or new subscribers.

Remittances can be made in any convenient way. Be sure to state whether you want this clock in Oak or Hand-Rubbed Mahogany.

Don't Guess!

A storage battery represents too much money to neglect it—battery troubles add too much to the cost of your car's upkeep. The

INDESTRUCTIBLE
MONARCH
Storage Battery Tester

will tell you when to charge your battery and it will save you real trouble and real money when it does so.

It is unbreakable. It is absolutely accurate. It is convenient to carry in your vest pocket—you can put it in your tool box with the rest of your tool kit—nothing can throw it out of adjustment. **And** it is guaranteed for 5 years. Pile up these points—and then invest the purchase price—

$1.50

You'll only need one—nothing can destroy it—and you'll always draw dividends from it.

FOR DRY CELLS

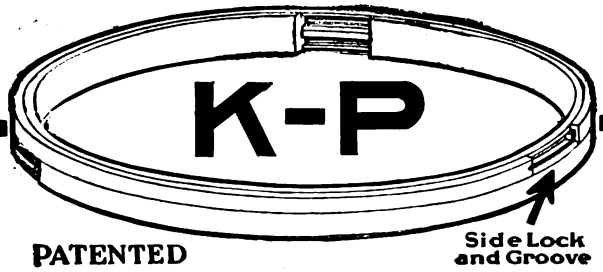
WHY K-P Piston Rings are Superior

K-P Piston Rings will enable your car to develop Maximum Speed and Power with Minimum Consumption.

K-P Rings are absolutely Compression Tight.
K-P Rings are Resilient and Flexible.
K-P Rings are Strong and Dependable.
K-P Rings are economical—pay for themselves.
K-P Rings prevent Excessive Carbonization.
K-P Rings are Easily Installed.

"Piston Ring Service is the Key to Perfect Compression."
—Efficiency Ed.

This cross-section shows the grooved construction which prevents the sections from slipping out of place or "riding" the pins and scoring the cylinder walls. Prevents the "vents" or slot openings from getting in line and allowing the leakage of Power and Compression.



Install a set of these mechanical efficient piston rings and notice the increased efficiency of your car.

Special inducements to Dealers and Repair Men.

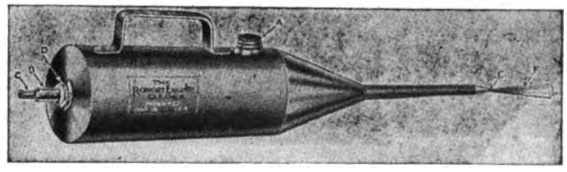
CLEAN OUT THE CARBON WITH STEAM



The Hart-Bell Carbon Remover cleans out the carbon with live steam. It is permanently installed on the intake manifold, and a turn of the handle admits a fine spray of water vapor that is instantly converted into superheated steam by the ignition in the cylinder. The steam loosens the carbon while the motor is running so that in five or ten minutes the carbon is blown out.

Hudson

ANNOUNCEMENT OF POLICY

The Hudson car will use a six-cylinder motor exclusively in all future models planned by this Company. Our refinement and development of the six-cylinder type of motor leads us to believe it surpasses in simplicity, low cost of upkeep, performance and general adaptability any other type so far developed for use in pleasure vehicles. We have built every type of motor—from one to twelve cylinders. The recognized ability of our Engineering Department insured that these motors would be the best of their kind in the present state of motor development.

The result of this research convinced us more firmly than ever before of the absolute supremacy of the Hudson six-cylinder motor. It is therefore more than pleasing to us to announce the continuation of the consistent policy which has marked our progress and advise Hudson buyers, both past and future, that they are securing the best engineering development that the industry offers.

ARE YOUR TIRES IN THIS JUNK-HEAP?

Don't Throw Away Your Half Worn Tires

It's just as unnecessary—just as extravagant—to throw away your tires when they become tread worn or rut worn as it is to throw away your shoes when the first sole gets thin, for you can get 5,000 miles more service out of them by doing what European motorists have done for the past three years. This will result in a saving of from $50 to $200 a year for you.

Don't Let the Junk Man Profit at Your Expense

That picture of the junk wagon—with its heap of cast-off tires—illustrates in a striking manner what becomes of the average rubber tire after 3,000 to 5,000 miles of service—uncertain service, with the nerve-racking dread of tire trouble.

This waste in tires is distinctly an American extravagance.

What European Motorists are Doing

The foremost European engineers have for years been studying the problem of getting more miles for less dollars. With their usual painstaking, scientific thoroughness, they experimented with tire protectors and steel-studded Treads. The result—for over three years European motorists have been "half-soling" their tires with steel-studded Treads just as we "half-sole" our shoes when the original sole gets thin.

These European motorists are getting from 10,000 to 15,000 miles out of a set of ordinary rubber tires, while American motorists are getting from 3,000 to 5,000, and—what is just as important—have almost entirely eliminated the constant dread of punctures, blow-outs and rim cuts.

Guaranteed 5,000 Miles Without Puncture

To many motorists this fact is of more importance than the money saved by eliminating tire repair bills—the constant dread of puncture or blowout spoils the joy of motoring. Each unnecessary noise—each bit of broken glass or sharp edged stone—each bump or "pop"—makes the man at the wheel think of tire trouble FIRST.

Durable Treads are backed by a signed guarantee—as good as a Government Bond—for 5,000 miles **without** puncture. Think of the joy of motoring when you KNOW in your own mind that your tires are **impervious** to the rough roads—when you KNOW that **you** won't have to get out and sweat fixing a puncture or blowout, besides, you save nearly enough to pay your yearly gas and oil bills, and the guarantee holds good no matter whether your tires are new or old, rim cut or rut worn.

How Does This Affect You?

The almost unbelievable waste in tires by the American motorist is not only national—it is vitally personal. It affects you—**your pocketbook.** Just consider what it would **mean to you** to get 10,000, 12,000 or 15,000 miles out of your rubber casings and at the same time drive your car without the constant dread of tire trouble.

In round numbers, it would mean a saving in tire miles sufficient to pay your yearly gas and oil bills—by the elimination of punctures, blow-outs, rim-cuts and skidding—a gratification which cannot be estimated in dollars and cents.

No More Skidding

Durable Treads are as sure-footed as a burro, and they're supremely convenient. Look at them—they're simply bound to be safe. The sharp-edged steel rivets make skidding almost impossible.

In London and in Berlin, as well as many other of the larger cities of Europe, ordinances compel the use of steel-studded Treads for public safety. Durable Treads are always on your tires—you don't need to worry about climbing out in the rain and mud to adjust your chains, and, **what is** more important—**you receive perfect non-skid service while your tires are protected instead of injured.**

Ask Yourself This Question

Do you intend to continue allowing the junk man to profit at your expense, by carrying away in tire miles enough to pay your yearly gas and oil bills, or will you turn to your advantage the experience of European motorists?

It is the same question of economy you decide when you "half-sole" your shoes instead of throwing them away when the first sole gets thin. Rubber tires cost several times as much as shoes and are certainly worthy of the same economy.

We Ship on Approval

We ship on approval to any motorist—without one cent of deposit—prepay the express—and allow you to be the judge. Durable Treads are easily applied in your own garage, without special tools, in thirty minutes.

If your tires are new then protect them from cuts and punctures by putting on Durable Treads at once—don't wait until they are all shot to pieces. **If they are old and rut-worn** don't sell them to Jimmy the Junkman—remember that "Durable Treads" are **guaranteed** for 5,000 miles without puncture—no matter whether your tires are old or new.

Special Discount Offered

To motorists in territories where Durable Treads have not yet been introduced we offer a special introductory discount equal to the full dealer's profit.

Will you let us give a demonstration at our own expense and risk?

Will you let us make you an offer so fair and square that you do not stand to lose one red cent, either before or after you buy? The time for action is NOW, before the tires on your car run another week in a "bare-footed" condition—before you get your next puncture or blow-out.

Cut out the coupon below. If you haven't a pen or pencil handy you can fill it out afterward, but cut it out now before you turn the page. It will be the means of adding at least 5,000 miles to the life of the tires on your car.

Atwater Kent

Perfect Ignition

Battery normal—Amount of charge represented by solid portion. Cranking, lighting normal; AK Ignition perfect.

Battery partially exhausted—Will not crank motor but will still light lamps and blow horn; AK Ignition perfect.

Battery exhausted—Will not crank motor or blow horn; lamps burn dimly; AK Ignition perfect.

Battery drained—No current for starter, lamps or horn; AK Ignition still perfect.

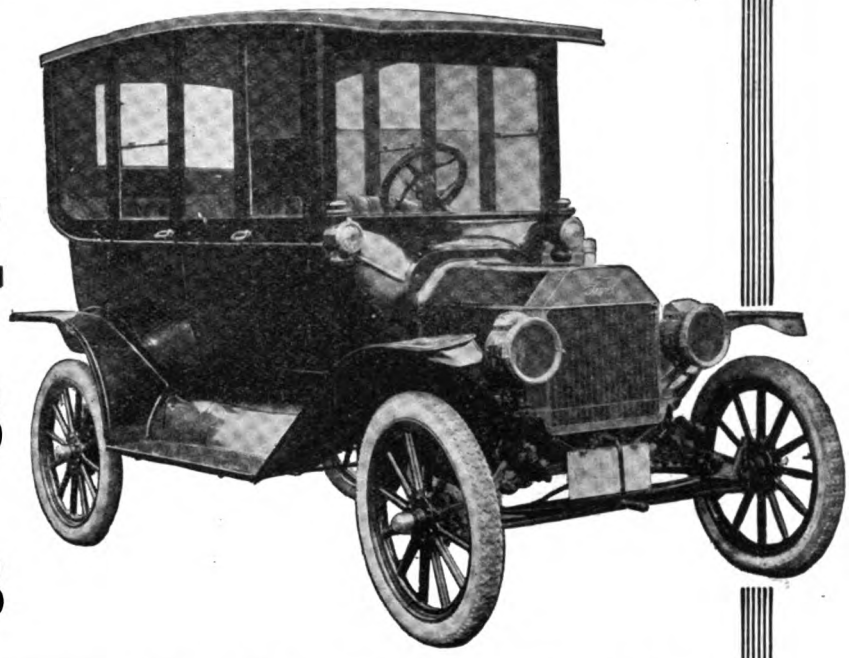
even with exhausted batteries.

Due to its efficient "open-circuit" principle, the current consumed by Atwater Kent Ignition is so small that it will not register on your dash Ammeter.

In fact, the storage battery on the car may be so exhausted that it will be too weak to crank the motor, light the lamps or even blow the horn—yet it will still provide the exceedingly minute current required for Atwater Kent Ignition.

Several hundred miles of steady, hot, dependable ignition, with batteries practically exhausted and generator disconnected! Because of this valuable feature the successful operation of your car does not depend on the condition of your storage battery.

By means of the Atwater Kent System with magneto replacement mounting any owner may bring his car up to date and obtain the same efficient ignition now standard equipment on thirty representative cars. Nearly 200,000 in use.



No matter whether you are a car manufacturer, engineer, dealer or owner we have valuable ignition information for you.

NOTE:—A special Atwater Kent System is provided for Ford cars.

Atwater Kent Mfg. Works
4933 Stenton Avenue, Philadelphia, U. S. A.

REAL LIMOUSINE AND COUPE TOPS FOR FORD CARS

$75.00 UPWARDS REAL BODY CONSTRUCTION BODY FINISH BODY EQUIPMENT

UNICO FORD BODIES

Most Profitable to Dealer BECAUSE

1 Our Agency Proposition is most liberal.
Agent secures real profits, not small commissions. Returns 3 to 1 over any other active seller.

2 Ford Owners are Discriminating and know real value when they see it. Unico Bodies win when the quality test is applied.

3 No Competition From Cheap Tops of cloth or imitation leather. Unico bodies are not makeshifts or flimsy substitutes.

4 The Only Complete Line.
A body for each model (Touring and Roadster) 1913-14-15-16 Ford.

EVERY FORD OWNER A PROSPECTIVE PURCHASER.

Unico Agents are making large, quick profits. Can you afford to miss this opportunity?

Most Profitable to Owner BECAUSE

1 Greater Value Dollar for Dollar.
Unico Bodies must not be confused with cheap material or imitation leather tops, as they are of best body construction.

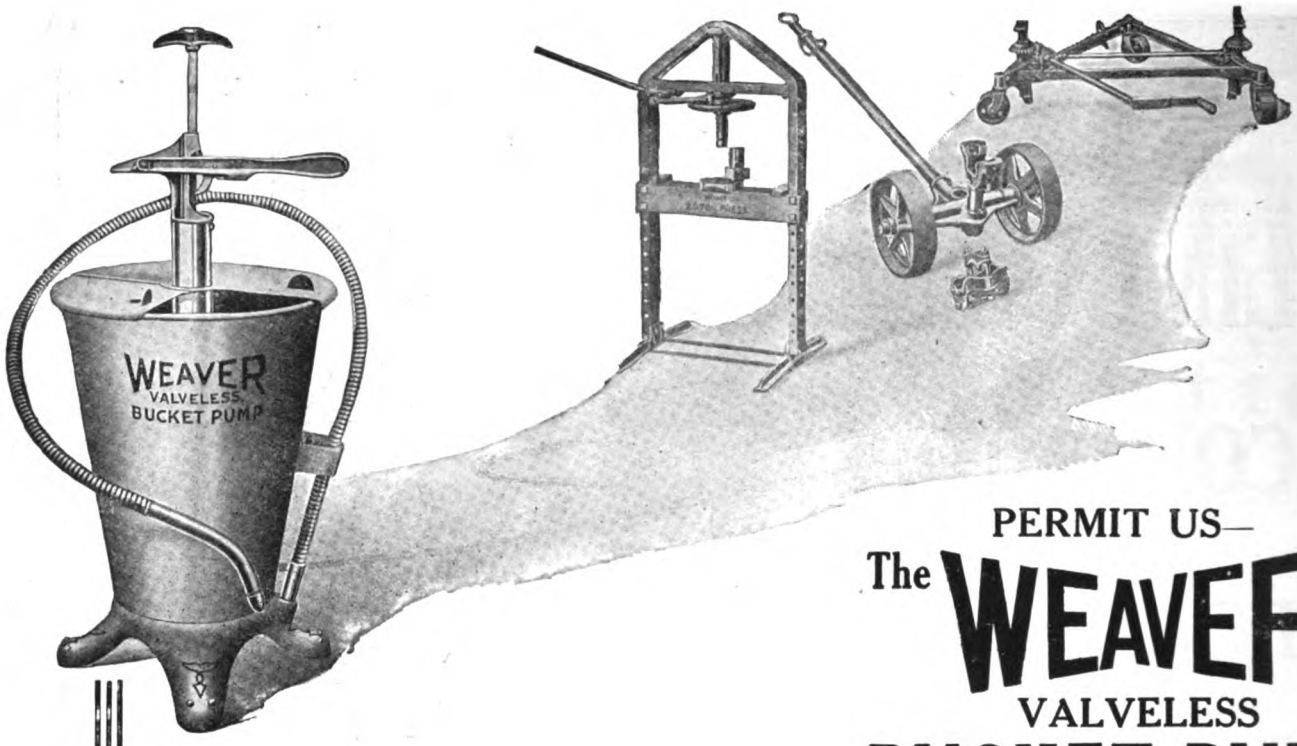
2 Construction Insures Durability.
Wood frame, metal panels, glass sash, minimum steel and hard wood, maximum glass. Strength combined with light weight.

3 Style, Comfort, Distinction.
Exterior seven coat coach finish. Interior full upholstered lining. Quality in every detail.

4 Equipment Complete, No Extras.
Adjustable windows set in rubber, electric dome lights, sedan doors. All necessary fixtures for quick attachment.

If you cannot locate a Unico Dealer, write at once for our Direct Sales Proposition.

WE ARE PLACING EXCLUSIVE AGENCIES



In every Town, County and City, East of the Mississippi River. If your territory is not already closed you may be able to secure agency for the most profitable Ford accessory of the season.

PERMIT US—

The WEAVER VALVELESS BUCKET PUMP

WHILE the Weaver Bucket Pump is amply capable of standing upon its own merits—we do not hesitate to point with pride to its long line of "blue-blooded" ancestors—confident that they will win for our infant prodigy instant recognition and endorsement among the most exclusive of the Automobile Fraternity.

The same originality and ingenuity which characterizes each article of "WEAVER" Garage Equipment is strongly evident in this Valveless Bucket Pump.

THE "THREE-WAY" FEATURE

One great advantage of the "Weaver" Pump is the fact that our valveless construction permits lubricants to be handled in "three ways."

First—The lubricant can be forced out of the bucket and into the desired receptacle.

Second—Grease or oils can be sucked out of the differential, transmission housing, etc., and **forced into the bucket.**

Third—Where the lubricant to be removed from the differential or transmission is of a different variety or quality from that contained within the Bucket, the barrel or chamber of the Bucket may be sucked full of the foreign lubricant and discharged again through the hose into a **third receptacle without disturbing the content of the Bucket.**

SELF-MEASURING

The barrel has a total capacity of exactly one pound of grease or heavy oils. In handling light lubricating oils which are usually sold by liquid measurements, ten full strokes of the lever handle will discharge exactly one quart.

STEEL HOSE

The Weaver Bucket Pump is equipped with ⅝-inch Flexible Steel Hose which is practically indestructible and cannot be affected by the grease.

CONSTRUCTION

The Bucket proper is made of heavy sheet iron and has a capacity of 25 pounds of grease. The barrel is of 16 gauge brass tubing, two-inch diameter, containing a plunger which will not leak and is impervious to the action of grease and oils. Shipping weight, 25 pounds.

List Price, - $12.00

700,000 Ford Owners have been waiting for this—→ It's Here!!

McQUAY-NORRIS LYNITE-PISTONS ALUMINUM

The aluminum piston has arrived. It's the latest sensation in the automobile industry—the most wonderful mechanical improvement engineers have hit upon in years.

LYNITE Aluminum Pistons are die cast by a patented process, the right to use which is possessed exclusively by the LYNITE Manufacturers. The most important of many advantages they possess over sand cast aluminum pistons is their exceptional strength and hardness—insuring great resistance to wear.

We are specializing in furnishing a set of four McQuay-Norris LYNITE Aluminum Pistons—

Completely Equipped with 12

LEAK-PROOF

Piston Rings

MADE BY McQUAY-NORRIS MFG. CO.

for Ford Cars. We are going to open up a market that covers one-third of all cars in use today in this country, advertising our proposition to Ford Owners Everywhere.

You know how many Ford Cars there are in your community. Every one of them a prospect for the Dealer who handles McQuay-Norris LYNITE Pistons, LEAK-PROOF Ring equipped. Every Ford owner is going to read or hear about them, and he won't pass up arguments in their favor like these:

McQuay-Norris LYNITE Pistons are two-thirds lighter than the ordinary cast-iron pistons he is using—that means quicker acceleration, higher speed, less vibration, lighter bearing pressure and longer bearing life. Friction is 50 per cent less—that means lower consumption of oil and saving of power. They are much cooler—that means less carbon deposit on the piston head and clean spark plugs.

This offer of ours is a bargain that was never offered to a Ford Owner before. The 12 LEAK-PROOF Piston Rings alone retail for $18.00. This means the four pistons are sold for the ridiculously low price of $12.00.

It's a combination that sells itself—a bonanza for any dealer that handles it. Get started on this early and secure the cream of the demand.

Send for new illustrated folder on LYNITE Aluminum Pistons—full of valuable information. Also FREE booklet—"To Have and to Hold Power"—explaining the merits of LEAK-PROOF Piston Rings.

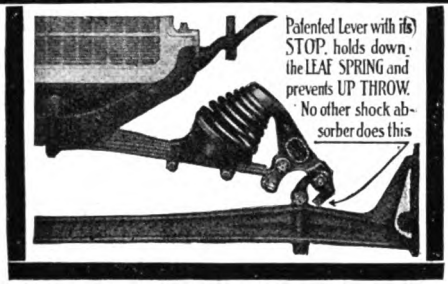
The Most Perfect Piston Rings Made

PERFECTION PISTON RINGS

They are made of soft, elastic steel in sections 1/16" wide and one section is required for each sixteenth in width of the groove. They give compression and power to your motor unequalled by any other rings. They present a barrier to the gas in the combustion chamber such as cannot be possible with a one piece ring.



This construction gives perfect compression, maximum power, minimum carbon, smaller oil consumption, lower gasoline bills, less smoke, and saving in repair bills. These rings are put on the pistons without being stretched, and this is impossible with one piece rings, which are always distorted when stretched over the pistons.

PERFECTION PISTON RINGS are made in all sizes and can be sold by dealers to great advantage. *Let us give you special quotations for your requirements.*

Moler & Steward, Mount Orab, O., July 1st: The Vulcanizer is working fine. We have had no trouble with it since we got it. ***It is doing fine work.***

A. M. Johnston, Mechanicsburg, O., June 1st: The machine is doing good work. I am well pleased with it.

W. D. Patrick, Elba, Alabama, May 20th: Am turning out quite a nice lot of work with the Vulcanizer. Well pleased with it.

Wheeler & Wheeler, Columbus, O., June 24th: We have the machine set up and doing fine work with it.

A Vulcanizer that satisfies others is a good one to start in business with. They do good work in our shop and they will in yours.

Catalogue on request.

VANDERPOOL CO. - Springfield, Ohio

A perfect one-piece Piston Ring

that has all the virtues of eccentric, concentric and more-than-one-piece construction; and none of their disadvantages.

A continuous ring cut spirally for half its circumference; heat-treated so that the free ends hug tightly together; the result is an absolutely *gas-tight* ring that uncoils in expanding, insuring uniform pressure and perfect contact with the cylinder walls.

The strongest gas-tight ring on the market, because of its simple one-piece construction, and, for the same reason, it costs less to buy, and less to install, for it is easier to put on and will not break in handling. Made of close grain cast iron.

Absolutely guaranteed; money refunded on any ring that fails to give perfect satisfaction after 90 days' trial.

Full description in free booklet.
Dealers and jobbers should write for interesting prices.

INLAND MACHINE WORKS, 802 Mound St., ST. LOUIS, MO., U. S. A.

Run Your Car All Winter On Old Tires Without Chains

You can run your car all winter long, anywhere and everywhere, over all kinds of roads, under all kinds of weather conditions, on the tires that you have on your car right now.
Motorists everywhere are fast realizing the worth of Treads, particularly for winter. *Eventually you, too, will see it that way. Why not this year?*

Don't Throw Away Your Worn Tires Like So Much Junk!

It is unnecessary, highly extravagant, and altogether uncalled for—Retread them at a LOW COST with "Pacific Fiber Treads" and cut down your tire expense $50 to $500 a year—Our free booklet tells you how.

In 15 Minutes your old tires can be made good for 5000 Miles more

—Guaranteed
—Puncture-Proof

Blowout-Proof —Skid-Proof—Rut-Cut-Proof—Rim-Cut-Proof—Oil-Proof—Gasoline-Proof—Tear-Proof—Road-Proof—Trouble-Proof

"Pacific Treads"
Are Not Leather Treads

Leather Treads, processed, treated or tanned as many times as you can imagine, will stretch and sag and being non-resilient can never resume their original shape again on the tire, once they are stretched. Pacific Treads on the other hand fit your tire like a glove and expand or contract evenly, smoothly and instantly—as little or as much as is required—never any more.

We Ship on Approval—Pay Express Charges—Ask no Deposit

Pacific Treads will save every motorist who uses them time, worry and expense. We will prove it to you at our own expense if you will fill out the coupon below. Mail it today.

Special Discount Offered to motorists in new territory on first shipment.

Ordinary Plug — *Two Plug Ignition* — SU-DIG Plug

MORE POWER GREATER MILEAGE

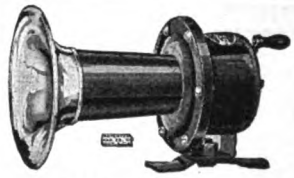
Show your customers how to ginger up their cars this winter!

There's no need of their "running like cold molasses," or of wasting gasoline, or of cleaning out carbon every week or two.

Quicker combustion, due to starting the flame from two points at once, **is a sure cure for cold-weather sluggishness.** One

SU-DIG SERIES PLUG

per cylinder, added to the regular plug, hastens combustion without excessive gasoline feed, thereby giving more power with a leaner mixture. No other change in system required; tap valve caps if necessary.



Su-Dig Plugs are nationally advertised and a profitable specialty. Write for booklet, "How to Get More Power," and special introductory offer for dealers.

CLEAN OUT THE CARBON WITH STEAM

The Hart-Bell Carbon Remover cleans out the carbon with live steam. It is permanently installed on the intake manifold, and a turn of the handle admits a fine spray of water vapor that is instantly converted into superheated steam by the ignition in the cylinder. The steam loosens the carbon while the motor is running so that in five or ten minutes the carbon is blown out.

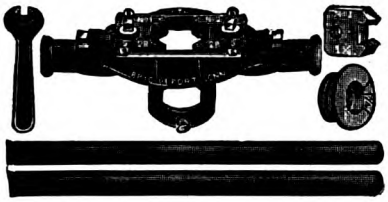
Add $250.00 A MONTH EXTRA To Your Business

REPAIR AUTOMOBILE TIRES

Sounds like a whole lot of money to clear extra every month. Seems almost impossible, but that is what hundreds of men are doing who have added a Tire Repair Department to their business. **The investment is small, the profit large** and **returns quick and all cash,** besides the demand for tire repairing and retreading is constantly growing. Your garage is by no means complete, your business is not as profitable as it can be until you get in on the Tire Repairing and Vulcanizing end.

THE HAYWOOD TIRE REPAIR EQUIPMENT

Answers all the requirements to successfully handle this end of the business. With it and a little business judgment, success is certain. Every year adds thousands of new auto owners. They are looking more and more to economical tire service. The day of discarded tires is over, the Haywood Equipment makes this possible.



HERE IS YOUR OPPORTUNITY

Either as a side line to your present automobile business or as a business by itself, the Haywood Equipment will make money for you. **Tires go wrong all the time.** You know that. Keep them in tune. Give your customers complete service —repair their tires and all. This builds business and makes you rich. Experience unnecessary. You can learn easy—or teach a boy to handle this end. Be the boss and make the money. Learn the details now. Investigate. Act quick. Be the first. Send name and address only. A postal will do.

The Foundation of this Tire

is just as good as the day it was bought. Any tire with good fabric, whether there is any rubber on the outside or not, is suitable for the

TRIPLE TREAD PROCESS

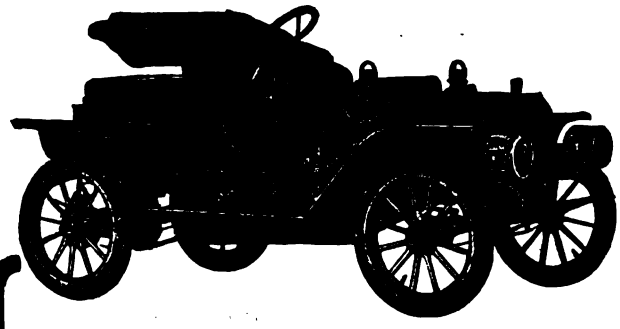
The Triple Tread is the only tire protector made

that does not depend on inflation, rim pressure or mechanical means to hold it in place, so that the style of bead on your tires cannot affect the success of their treatment.

In Vulcanizing the Triple Tread on your Tire

we are able to fill the pores of the leather with rubber, making it waterproof, so that by bringing the leather down the sides and over the bead of the case, covering it completely, we are able to keep dirt and water from getting under the tread to rot the fabric, and also to strengthen the sides and bead of the tire.

Write for our booklet,



"Worn Out Tires Made New."

Please mention the size of your tires.

TRIPLE TREAD MFG. CO.

"Evernew" Auto-Top Sizing is necessary as the first coat on unpainted cloth, mohair or canvas.

"Evernew" Auto-Body Enamel in colors to correspond with our "Evernew" Auto-Top Dressing. Special shades to order.

Make the Grease *Stay In!*

Grease—or oil, for that matter—has a wasteful faculty for squeezing out of apparently tight places. And in a transmission, for instance, where it's churned continually, it defies most packings—first, by squeezing past them, and also by eating away the packing itself.

ENDURA SHEET PACKING keeps grease or oil in because it is made specially for that purpose—grease, oil, gasoline and hot or cold water cannot affect it. Successful, prolonged use on thousands of cars has proved this.

Send the coupon today for free samples of **Endura**, and interesting chart, "How to Pack the Car" and other interesting data.

COMING—Auto Storage Season

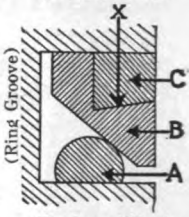
Owners will soon store their cars, and it is as much to your interest as the owner's, that these cars be protected.

KENNEDY AUTO STORAGE COVERS protect cars from Dirt, Dust, Cold and Moisture. These covers are made from a heavy imported paper; are securely reinforced to prevent tearing, and completely cover the car.

KENNEDY AUTO STORAGE COVERS also protect tires and preserve the life of the rubber by excluding light.

BE THE FIRST in your locality. Get further particulars today; interesting profit and sales easily made. Do not delay—delay means lost sales. Write to

The Kennedy Car Liner & Bag Co., Shelbyville, Indiana.



Pressure Proof Piston Rings

stop oil troubles because they take up side wear in piston groove by means of the spring expander acting on the bevel on the under side of the ring. This feature appears in no other piston ring.

They are made of soft cast iron, no steel or composition to score cylinders.

Ever see a piston ring that would give perfect service after being broken? The Pressure Proof is the only ring that will do this. Let us tell you how.

(Pressure Side)

(Section of Ring)

The Pressure Proof Ring will give longer service and higher efficiency than any other ring made, regardless of price or construction.

Install a set of these rings at the next opportunity. We guarantee that you will make a discovery about piston rings.

Write now for particulars and dealers' proposition.

Complete Repair Outfit

Every GARAGE, PUBLIC or PRIVATE, needs this BIG, STRONG, EVERLASTING COMBINATION OF TOOLS which we call the

STEWART HANDY WORKER

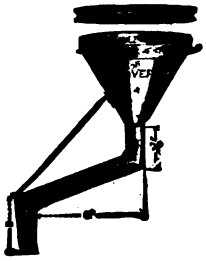
Weighs Boxed 90 Pounds

Price Complete Only $12.50

If you bought all the tools you get with it, of the same high quality, strength and durability, and the equipment to operate them, they would cost you at least $25 at wholesale price.

Each one a tool you can use every day to save time and money. A complete, compact workshop that you can attach to a table or bench anywhere about the garage and make it pay you big profits. It will enable you to quickly and easily do any ordinary repair job.

NOTE WHAT IT INCLUDES



A strong, practical anvil; powerful vise, up to 4½ inches, width of jaw 4 inches; a sure-grip steel pipe vise, takes up to 1¼ inch pipe; a Corundum grinding wheel, 5 inches x 1 inch; a two speed drill press with 2 drills; a metal cutting wedge and driving mechanism of three speeds—direct, 4 to 1 and 16 to 1—easily regulated by changing the handle grip. It operates grinding wheel, small circular saw, buffing wheel and many other similar tools. With the Stewart "Handy Worker" you can do your own automobile repairing, etc., blacksmith work, home repairing, make plumbing repairs, keep knives and other cutting tools sharp and in good working trim.

Send for one of these great combined outfits today with the understanding that if you don't like it in every way you can ship it back and we will return every cent you paid out. Of all the thousands shipped, not one customer has made a single complaint. It pleases every customer, but our standing offer to return every cent paid out holds good to each purchaser.

SEND ONLY $2.00 WITH YOUR ORDER and pay the balance when it arrives. ORDER TODAY OR WRITE FOR BOOKLET.

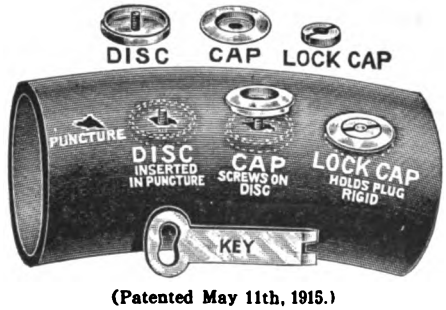
SPITLER PUNCTURE PLUGS

The Spitler Puncture Plug repairs punctures in automobile inner tubes quickly and without the use of cement, assuring a safe, permanent and economical repair.



The operation is so simple that a lady can make the repair without soiling her hands.

The plug can easily be taken out and used over again. A permanent repair in one minute.

To insert The Spitler Puncture Plug into the puncture, wet the tube before inserting plug.

Place the base of plug on edge and by stretching the tube at point of puncture, the plug slides in like a button in your coat. Then place cap over discs and screw lock cap firmly.

The Spitler Puncture Plug positively cannot cut the tube nor injure the fabric of the shoe for the principle is the same as the air valve on the tube.

Write for Circular.

Price—Four to a Set, $1.00.

Woodworth Light Weight Overshoes

THE IDEAL NON-SKID TIRE EQUIPMENT

MADE With Special Quality Steel-Studs That Hold Firmly On Asphalt Or Brick Pavements

Woodworth Overshoes not only prevent skidding but they protect the tires from all outside injury and road wear: they do away with punctures and can be used continuously so that one is always ready for slippery places.

With a set of Woodworth Overshoes over good tires, you can feel sure you will not have tire troubles in bad weather: you can feel you are always ready for slippery roads and you will save your tires enough to pay more than the cost of the Overshoes.

Woodworth Overshoes make an excellent equipment for use over spare tires on demountable rims. They protect the tire from the action of light and air and if used over old tires they reinforce them to a considerable extent, preventing blow-outs. On slippery days, the spare tire with the Overshoe on can be substituted for one of the regular tires for use as a non-skid.

Woodworth Overshoes are very light and resilient so that they do not consume power or affect the riding of the car. They are low in price, costing but little more than twice as much as tire chains and they will wear many times as long.

The leather used in Woodworth Overshoes is waterproofed by our special process and is guaranteed never to absorb water and become stretchy. On this account there is no danger of them becoming loose to chafe the tires. The leather on the inside is finished in such a way that it adheres to the rubber of the tire, preventing friction and wear.

On clincher tires the treads are fastened with small hooks which engage the clincher rim. On straight side tires, they are held with a very thin, strong bead that fits between the bead of the tire and the rim. They can be put on as easily as a tire shoe can be removed and replaced.

Full instructions sent with every Overshoe. Send for description and prices.

Sent express prepaid on approval to any part of the U. S. or Canada.

LEATHER TIRE GOODS CO., SOLE MANUFACTURERS NIAGARA FALLS, N. Y.

Canadian Factory: Niagara Falls, Ontario.

NEW YORK DISTRIBUTOR, A. W. Rosen & Co., Top Floor, 610-614 Broadway, New York City.

Every Automobile ought to carry a set of Easyon Chains

The user can then feel that he is always prepared for slippery places: for he can put his chains on whenever he finds he needs them even if he is up to the hubs in mud.

Easyon Chains are individual chains which fasten to the spokes with leather covered fasteners having a snap at each end for holding the cross chains. They will not injure the paint or rubber of the tire.

With Easyon Chains you do not have to use chains continuously in wet weather, wearing out both chains and tires rapidly, for you can run with bare tires, feeling sure you are always ready for slippery places.

Price $3.20 per set for tires up to and including 4 inch.
Price $4.00 per set for tires larger than 4 inch.

Sent prepaid to any part of the U. S. or Canada.

A JOURNAL OF PRACTICAL MOTORING

Registered in the U. S. Patent Office

VOL. XX, No. 3. NEW YORK, NOVEMBER, 1915 PRICE { 10c PER COPY $1.00 PER YEAR

WELDING INFORMATION.

Some Concrete Examples of Simple Jobs That Require Care Only.

From J. N. Bagley, Nebraska.—It may seem that one is overdoing the welding articles when they appear as often as they do, but if we could see the unsuccessful operators over the country who have good machines we would all feel an interest in them. I have visited the smaller villages and towns and find many machines that have been sitting in the corner for many months. On making inquiry as to why they were not used I have found a number of reasons, but the most important was the fact that the operator could not get the necessary instructions, and had neither the time nor the money to get out and visit other plants where the operators were successful. One operator told me that all the cast iron he welded broke again in a short time and his customers had ceased to bring the castings to him, and he wanted to know if there was a way to avoid it. I asked him if he had some of the broken pieces and he went to the rear of the shop and brought a number, all of which had broken in the weld. He also had a few that were not broken, but they were

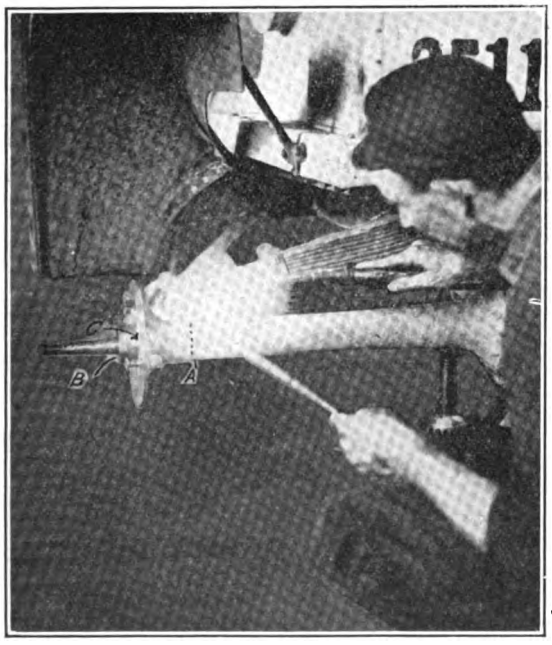

Fig. 1.

so out of their original shape that they could not be used.

Now this brother wanted to do the work but had given it up because of the lack of knowledge as to the proper handling of the outfit. The castings which broke were due to two things in particular; one was that he did not weld entirely through from both sides and the other that the flame was not properly adjusted. During my stay of a little over a half day we got the welding plant out and dusted it off, and put it into working shape and set about to reweld a few pieces that he had welded. Then we called the customers to whom the castings belonged and asked them to give them another trial, which they consented to do. They were just as

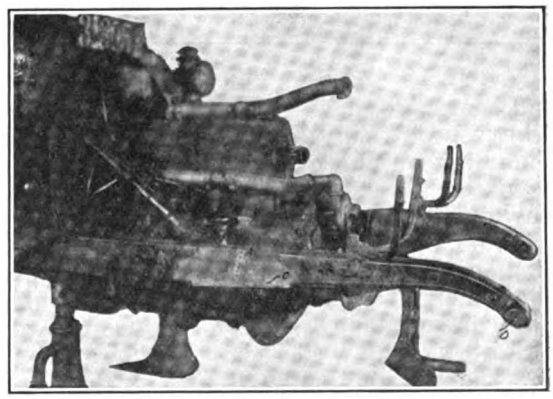

Fig. 2.

anxious to see the machine a success as he was, because it meant dollars to them in a busy season as it did to the person operating the machine.

Three months later I called on this same brother to see how he was progressing with the work, and when I drove into the shop yard I found a large traction engine standing near the shop door and he was welding a couple of teeth in the traction gear. I watched him until he was done, and he was glad to see me again. He told me that from the day I had helped him to get started he had improved and no more dust had accumulated on his machine. The teeth he placed in the gear wheel were good enough for anyone, and when dressed up could hardly be told from the teeth beside them. He also said that if I could have had some one to give him a few ideas in the beginning, he would be many dollars ahead. I advised him that he do as much for some other brother when he found him in trouble as I had done for him.

The possibility of the welding machine is almost unlimited especially in a general repair shop or a garage, and the photographs shown will give a few ideas as to some of the jobs that are possible. The writer receives every few days a personal letter from some reader of this magazine asking for information. I have always taken the time to answer the letters and do what I can for them.

Fig. 1 shows a job being done on a Ford rear assembly without removing it from the car. The cost to remove it from the car would be quite a little to say nothing of the time lost. The brake band and spring, C, were broken loose from the housing proper, and to remove it and replace with new rivets would be some little job. The wheel was removed as well as the brake band, leaving the balance as

Digitized by Google

shown. The roller bearing and sleeve were drawn from the end, B, so that the heat would not interfere with the temper. As shown at dotted line, A, the housing was welded entirely around with Swede steel wire, and at C, on the outside, making the job as strong as before.

Now where the rivets went through was welded over to prevent the grease from working out and making the car look bad. The job was finished in a short time and the customer went on his way, while

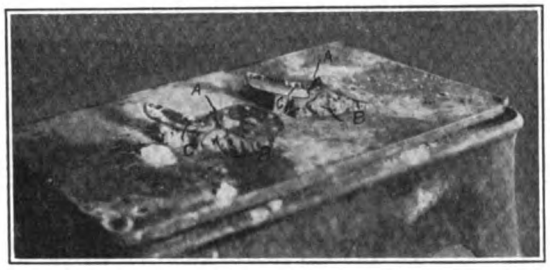

Fig. 3.

if it had been necessary to place a new part the cost would have been many times higher.

In handling things of this sort where the steel wire is used, the flame should be adjusted so that the sparks will not fly from the molten metal. The torch should be moved in a backward and forward direction, so that the flame does not get any one place hot enough to burn the metal, as in so doing the parts will be weakened. When the temperature is about right and the weld rod is touched to the work it will stick as though it was a magnet. It should be worked at about this sticky temperature, as we call it. A good flux aids considerably and can be purchased along with the balance of the welding supplies.

In Fig. 2 we have a more difficult job, and yet it is just as simple as the one just mentioned if done as it should be. Both sides of this frame were broken, as shown at A, letting the front engine support carry the load. This car was driven over a hundred miles with both sides of the frame in this condition. It is best to use a reinforcement beside the welding, where it is possible, and there will be no danger whatever of the welding part breaking again. In this instance on the under side of the frame was placed a bar of steel $\frac{3}{8}$ of an inch thick, wide enough to come flush with the outside of the frame and a little wider than the frame on the inside, say one-fourth inch. This permits the frame to be welded to the bar with ease. Large jacks were placed under the car as shown leaving the ends without support. At the extreme end, at D, a force was applied until the crack was entirely closed and the bar of iron, B, made fast with two bolts to hold everything in place while welding. When all was made secure the frame was welded to the bar at C, inside and out and across the ends. Now with a cape chisel the crack was cut out in a V shape entirely through. This allowed for the new metal to be filled in. In case the reinforcement can be placed inside the frame it would be better, but very seldom this can be done as a frame generally breaks where a cross member is found or where holes are drilled in the frame. This entire job was done at the expense of $7 to the customer, while if he had purchased a new frame and placed the machinery in it the cost would have been not less than $100, to say nothing of the time lost. This job when painted up and the fenders were in place could not be noticed unless one were looking for it, and so far as strength was concerned it was stronger than the original frame. A few jobs of this sort, scattered over the locality, are a very good advertisement for the welding machine and the person operating it.

Fig. 3, for the beginner, may seem a trifle more difficult to handle, as it is brass. Brass handles a little different than cast iron or steel, and care should be taken that it is not overheated and ruined, as it melts very easily with one of the larger tips. The parts in Fig. 3 are windshield hinges and there are many of them for repair. For some reason new ones cannot be had when wanted, especially if the old shield is out of date, so to speak. In the first place, take a ball of clay, damp enough to cling together well, and bed the broken parts into it in their original shape, as shown at B, with clay, C. A is the crack to be filled with the metal. It is a good plan to use a small tip which will heat only the parts close to the crack. Use a spelter wire which will melt easily. Now play the flame along the crack, A, quite close until the metal melts and blows out a little. Have the wire heated and fluxed, and immediately place it in the crack. As soon as the flux strikes it, it will unite at once. Raise the flame and melt the wire into the crack until it is higher than the casting and let cool of its own accord. Never

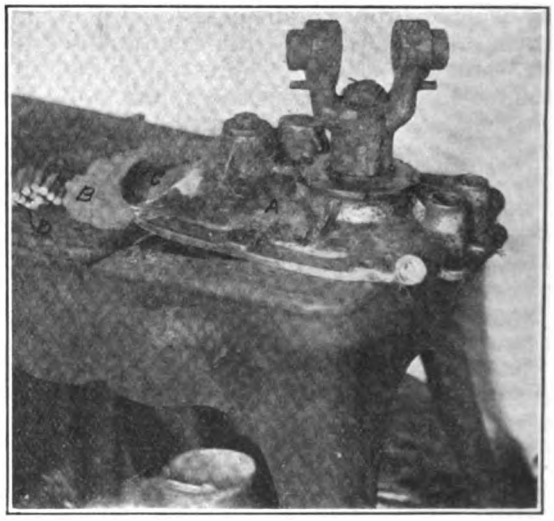

Fig. 4.

dip, as it softens the casting until it will not have the strength. If after taking the casting from the mold it has a crack on the other side, take a fresh ball of clay and bed it down into the clay as before and repeat the welding operation from the other side. Allow it to cool and file to shape. If possible leave it a trifle heavier than it originally was. The brass casting will be very easily worked if time and patience are taken to make preparation and the flame is small enough so that it does not heat too far each side of the crack.

Fig. 4, we have something a little different, and sooner or later every operator will come up against this as many times the broken pieces are lost and it is necessary to "puddle" in new, as we call it. To do this it is necessary to make a form or mold to hold the metal in place as it is run together. At A we have a portion of a transmission case with a part of it gone as shown. At C we have the space to be "puddled" in. Around the outside edge we build a

Digitized by Google

form of clay which will serve as the outside diameter of the case when finished as shown at B. D is a small bundle of weld rods broken in short lengths to be placed into the mold and melted, as it would take too long to feed the metal into the space with the weld rod, and some of the metal would be over-

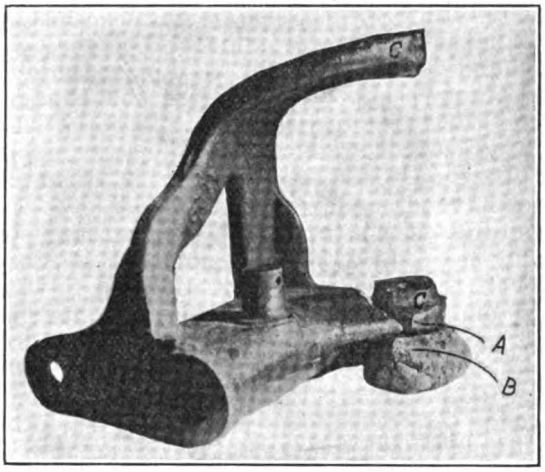

Fig. 5.

heated. The metal should be heated just hot enough to fuse well for if heated too hot it will have hard places in it and make the machining difficult. In case there are holes in the edge of the casting to be preserved it is not a bad idea to fill them with clay, and when the job is finished the clay may be removed and the holes will be in place. Care should be taken in a job of this kind that the puddled metal is firmly united with the balance of the work as flowing it in is not sufficient. This should be allowed to cool entirely in the position shown, as if removed from the table while hot it would either warp or cool with hard spots in it. I have found a very good plan to handle a job as shown is to cover with air slacked lime as soon as finished and leave until entirely cold. This takes much longer time but adds a great deal to the quality and strength of the material. The table shown in Fig. 4 is a base of an old cream separator with a planed block of cast iron placed on it. This can be moved about with some ease and the cover adjusted to any angle by blocking up under it.

In Fig. 5 we have a casting from a mowing machine that was brought to the shop by a farmer in a terrible hurry, as most farmers are in a hurry

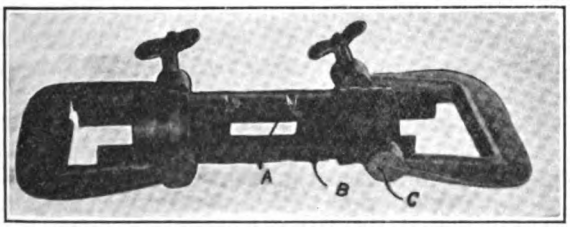

Fig. 6.

during their busy seasons. The casting was welded in less than an hour and the farmer went on his way rejoicing. The casting was broken at A and ground to the V shape as shown. The clay was used as shown at B to hold the parts in place. A rod nut shown was passed through the hole from C to C, which kept the parts in exact alignment while welding. After the job was welded up as shown it was turned over and welded from the opposite side, as there was no danger of it getting out of shape, and the rod passing through C, C, held it in place. Farmers appreciate jobs of this kind. In building large V notches of this sort, play the flame along the edges of the break from one side to the other, until the metal is in a melted condition, then dip the weld rod into the flux and apply it to the edges until the metal is melted. Now by playing just enough heat on the casting and the greater amount on the weld rod, the metal can be builded in without danger of flowing it out at the sides. When the metal will run out at the sides of the casting it indicates that the flame is played too strong on the casting and not strong enough on the rod. In placing teeth in a wheel, etc., this will be noticed more than anywhere else, for if the heat is not properly distributed, it will cause the metal to run down the sides and it will be difficult to remove. With practice a tooth can be builded an inch above the wheel so perfect it will hardly need dressing to mesh into the tooth on the wheel running it. This is all in controlling the flame and watching that the metal does not get too hot. Metal handled carefully as described will remain soft enough to file easily.

In Fig. 6 we have a part of a steam pump broken as indicated at A. Both sides being broken it was necessary to hold it perfectly straight and this was done by placing along either side heavy straight bars of steel as shown at B. These bars were clamped tight to the pump with two clamps, C. The space below the notched part, A, was filled with clay

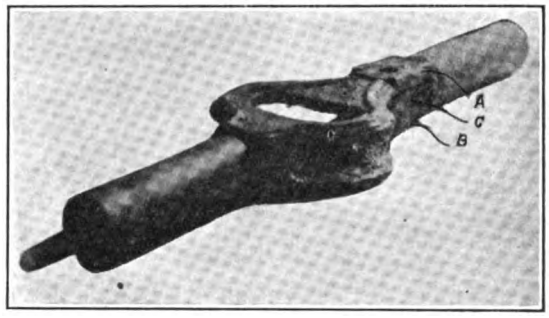

Fig. 7.

to prevent the closing or changing the opening. The welding was done in the usual manner, care being exercised to heat the metal only hot enough to fuse as there was some filing to do before replacing the cylinders in the pump.

Fig. 7 we have another part of a steam pump which was broken as indicated at A, the side, B. remaining unbroken. The part of the casting broken out had a small hole in it but not being able to line it exactly it was welded solid. The piece was supported in position by clay at C while making the weld. After welding the casting was turned over and a drill the proper size was run through the hole on the opposite side, coming through the part welded in leaving both holes in exact line to receive the pin which worked in it.

The writer has found best to use only cast filler rods on the cast work as it gives much better satisfaction than using the brass. Tobin bronze works very well on the castings made of malleable, while there are malleable filler rods that answer well in ordinary cases. It is a good plan in welding malleable casting to reinforce either with a steel patch or with an excessive amount of metal where possible.

I trust that in preparing these articles some reader will be benefited by them and that some un-

successful operator will stick to his machine until such time as instruction comes to his aid that will start him on the right track, which will result in a profit both to himself and to his customers.

TWO CYCLE ENGINES.

Mr. Duryea Passes Over the Fact That They Have Been Tried and Found Wanting.

From Charles E. Duryea, Pennsylvania.—Your reply to B. Weems about the 2-cycle engine seems to have been not fully considered. While based upon experience with the common or garden variety and quite correctly representing the usual results obtained therefrom, it is far from stating the actual facts. I confess to a feeling against the 2-cycle equally strong at one time, but I have seen 2-cycle engines that were really good and what can be done once can usually be done again.

There is nothing in the 2-cycle design that prevents it functioning as well as the 4-cycle if it is as well perfected and made. On the contrary, it has less parts, less friction load and so may be more economic. It holds the hot gases a less length of time and so can be cooled easier. That it must exhaust earlier is incorrect. In both cases the exhaust must get out before the piston starts back or there will be negative work. By having a light check in the transfer passage there is as much time after dead center for the new charge to enter as before for the exhaust to get out, so the 2-cycle can be given the same timing as a 4-cycle so far as the exhaust is concerned. Usually the timing is somewhat earlier, as you correctly state.

That this early opening of the exhaust is a loss is not necessarily true. Did it ever occur to you that it expands its working charge as far as it compressed the new charge, whereas a 4-cycle always opens its exhaust many degrees ahead of the point of beginning compression? The 4-cycle compresses 180 degrees and expands about 130 degrees. The 2-cycle compresses about 125 degrees and expands the same. That the compression pressure may be the same, the compression space must be smaller. Most folks overlook these facts.

There is no difficulty about getting the exhaust gases out. Their own energy will take them out several times if permitted free action. Indicator cars of the 4-cycle exhaust often show several waves of vacuum and pressure during the expelling stroke of the piston. The gas goes out and comes back again. So there is needless time and friction in this expelling stroke.

Let us study the matter a little. The new charge goes direct from the carburetor into the cylinder of the 4-cycle and too often the fuel never gets vaporized. I have seen liquid gasoline running from the muffler of a cold 4-cycle engine. Not much of course but enough to know that the fuel went through without burning and continued to do so but was not visible because the parts and pipes became hot enough to vaporize the fuel. Then nose instead of eyes told the story. The waste went on. But in the 2-cycle the liquid largely stops in the crank case. This case is usually big enough to hold 3 to 5 charges at a time. Of course as one is transferred another is admitted, but the effect is that much of the new charge remains, and the average is that the charge sent to the cylinder has been exposed to the motion and heat of the crank case during several revolutions, and so is better vaporized and more powerful and economic than the usual 4-cycle charge.

If the ports and deflector are right the new charge is thrown to the head of the cylinder and pretty well spread out there so that very little if any of it gets to the exhaust port. This is particularly true if running at part throttle, which is the usual auto custom. With a proper size of engine there is not often call for full power and so the small charge that is admitted does not fill the top of the cylinder and does not escape. In boat use full charges are used and there is much escape. Any one can test this by noticing the exhaust. The rank odor of a wasteful exhaust tells the facts. A good 2-cycle does not have this odoriferous exhaust.

The crank case is not a good pump and so does not draw in quite such large charges as does the cylinder of the 4-cycle, but when drawn in they are warmed and expanded, and so have somewhat increased in volume before being used. Moreover, since full charges are seldom used, they are large enough. If not, let a slightly larger engine be used. As already explained, the cool gases rush in and crowd the hot ones out. This cools the walls from the inside and finishes vaporizing the new charge. Such heat as goes into the new charge is there ready to do work on the down stroke. This adds economy. Then the compression is always constant. The early makers of stationary gas engines did not attempt to throttle because this reduced compression and economy so much as to be considered very bad. The auto man ignores the loss of economy and throttles that he may get smooth action. But the 2-cycle with its constant compression, gets the most economic condition possible. If the cylinder does not fill with the new charge it fills from the exhaust. It then expands to the full length of the compression stroke instead of about three-fourths that far. This is what every gas engine man wants.

Most people say it has one fault, in that it will not idle like a 4-cycle. Surely the exhaust gases dilute the small new charge till it does not ignite as does the almost uncompressed but more nearly pure charge of the 4-cycle. But every user of a 2-cycle has noticed that if he cuts out half the sparks it idles beautifully. What has the cutting out of the sparks done to the mixture? Simply this. The remaining cylinders must do double duty and so they take charges large enough to fire every time, just as do the charges in a 4-cycle which having half its strokes idle must do double duty on the working strokes. Even at that the advantage is with the 2-cycle because it has no cam shaft and valves with their springs and friction to act as a load and require still larger charges.

It is very easy to make 2-cycle engines of the auto sizes that will pull well at 3,000 r.p.m., and develop their maximum power at 1,400 to 1,800 r.p.m. Surely no one need complain about such speeds.

These remarks refer to the crank case compression types. By adding the complication of a compression cylinder, much better results can be obtained but probably not proportional to the added cost and parts.

So long as we are adding nearly as many new buyers per year as there existed users before, it is hard to get a new thing introduced. The new man naturally follows precedent and buys what he finds in use. Some of these days we will find the market

Digitized by Google

filled and then makers will begin to cater to the experienced man and he will want to know why he must carry 4 cylinders to do poorer work than 2, and eight valves to do work where none are needed. Then the 2-cycle will begin to come to its own. About that same time people will also ask why we should muss around with water and radiators when the air finally must absorb the heat anyhow and when the air cooled cars are holding all records for economy and efficiency? The only answer is PREJUDICE.

DRY BATTERIES.

Their Lasting Qualities for Ignition and for Lighting.

BY SYDNEY F. WALKER, M. E.

No. 6.

The dry cells of the Le Clanché type are supposed to give 1.5 volts when they are new. They rarely give more than 1.4 volts on open circuit, and when being discharged the voltage falls. Perhaps a point in connection with this had better be cleared up. The 1.5 volts of a dry cell is only furnished when

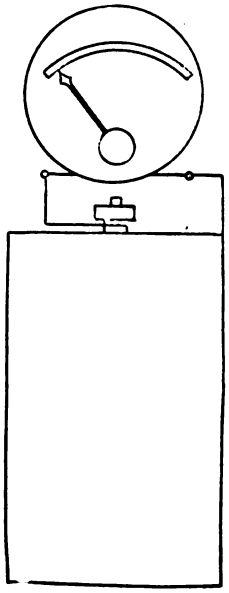

Fig. 18—Diagram showing the connections for testing a dry cell with a small voltmeter.

practically no current is being taken from the cell, or say only the very small current required to measure the pressure across its terminals, with a high resistance voltmeter. Some of the voltmeters that are employed for testing small batteries of accumulators and dry cells are wound to a comparatively low resistance, so that the current passing out during the time the cell is being tested is comparatively large; and hence the pressure as measured by those small voltmeters is usually in the neighborhood of 1.3. The useful pressure furnished by any battery, or for that matter by any source of electricity is of course the pressure obtained when the useful current is flowing. Where a battery is to furnish current for lamps, we have to take the resistance of the lamps, and the resistance of the battery and the pressure of the cells during the time the current is passing. To put the matter in another form, if we know the current which has to pass the resistance of each cell and the resistance of the lamps, we can find the number of cells required. Or again having the resistance of the lamps, we can find the resistance which the cells must have and their number in order to furnish the requisite current.

Now as to what batteries will do. The present writer made some experiments some months back upon an ordinary quart wet cell Le Clanché and a

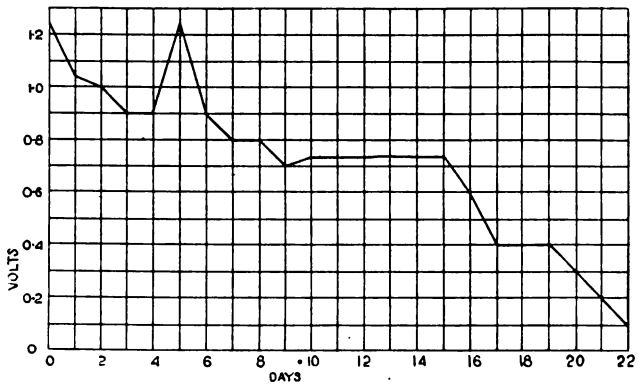

Fig. 19—Curve showing the gradual fall of pressure of a wet Le Clanche cell under the test mentioned in the text.

number of dry cells of various sizes. The test was conducted on the same lines as those which he made a good many years ago to obtain a good working cell for the work of those days. A large number of cells of various types were included in one circuit with an artificial resistance, a length of copper wire so that a small current was continually passing through them. The cells were kept in the test for about three weeks and the pressure between the terminals of each individual cell was tested every morning. The writer gives the curve of the wet cell as a sort of standard, then the curve of a cell which he believes was made in Germany, and which gave very good results.

The wet cell, it will be seen, started at about 1.25 volts, dropped to 0.9 in four days, then rose to 1.25 again, and then fell more or less continuously, till at the end of three weeks the pressure was practically gone. The German dry cell, of which the curve is given in Fig. 20, it will be seen started at 1.40, it fell to 1.25 in one day, maintained that pressure for seven days, then fell again to 1.1 in one day, and then maintained the varying pressure shown. The writer's object in showing this last curve is to enable it to be seen that a cell made on the same lines as the German, when furnishing a certain current, would keep its pressure practically constant for something like two weeks, and therefore, as ex-

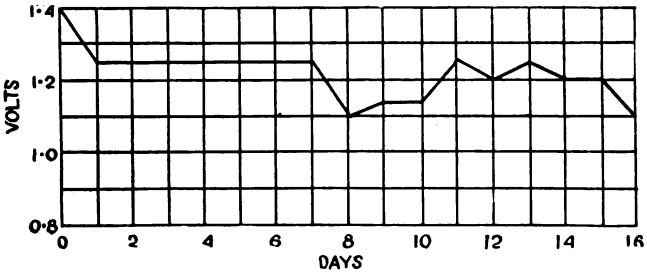

Fig. 20—Curve showing the gradual fall in pressure of an Obach dry cell under similar test to that of the wet cell.

plained above, if the quantity of oxide of manganese and salammoniac and the general dimensions of the cell are proportioned to the work there is no reason that cells should not last for three weeks at any rate when doing all that is required of them for lighting and for a longer time if they are made in

Digitized by Google

larger sizes. It appears to him that it would be much simpler to have a battery of cells working in this way and changed when the lights ran down than to have all the trouble of looking after accumulators, dynamos, etc., required with that arrangement.

In Figs. 22 to 25 the curves are given of some cells made by the Western Electric Company and tested at the National Physical Laboratory in London. The writer gives these curves as they show in a very striking manner what dry cells will do. The test to which the cells were submitted is again a very practical one. Six of them measuring 6¼ inches high by 2½ inches diameter over all were connected in a circuit including a resistance of 5 ohms, as shown in Fig. 21. The cells were connected

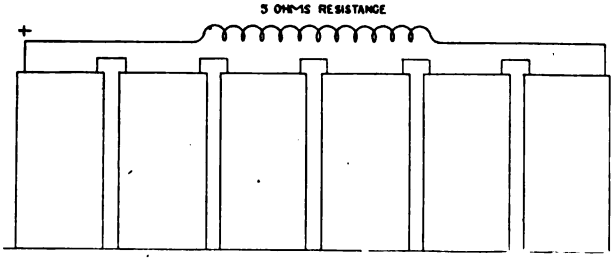

Fig. 21—Diagram showing the connections for the test of 6 Blue Bell dry cells in series at The National Physical Laboratory.

to the resistance for six hours per day, resting the remaining twenty-four hours. This is a pretty close representation of the work that cells would have to do in furnishing current for the lamps of a motor car. It is probably in excess of the average, though six hours work might be required of them in winter time. The cells also rested on Saturdays and Sundays; this rest would probably make up approximately for the difference between the time usually required for lights on a motor car and the six hours test. In a great many cases the writer believes the time the lamps would be required would be smaller.

Fig. 22 is a curve showing the variation of the internal resistance of the cells. It was mentioned above that cells lose their power in two ways by decrease of pressure and by increase of resistance. In the figure the vertical distances, the ordinates as they are usually called, represent the resistance measured in ohms, and the horizontal distances, the abscissoe, the number of days the cells were at work. It will be noticed that at the commencement the cells had a resistance of about 0.5 ohm each and that the resistance decreased slightly at first; this would be due to the percolation of the liquid from the sal-ammoniac into the manganese portion; that it remained fairly constant for twenty days, then rose slightly and continued to increase until the end of the test. For practical purposes there was no increase of resistance for three weeks. This bears out the test made by the writer upon the German cell which showed that it could be depended upon for two weeks at least.

Fig. 23 shows the pressure furnished by the cells on open circuit. It will be noticed that the curve zigzags very much. It commences at a little over 1.5 volts, falls to a little under 1.4 in a few days, rises slightly, again falls, rises slightly again, and so on. For practically six weeks the open circuit pressure, it will be seen, did not fall below 1.2 volts.

In Fig. 24 the curve shows the pressure on closed circuit, that is to say, when the cells were connected up to the resistance. It will be seen that the pressure commenced at a little over 1.4 volts, fell exactly as the open circuit pressure did during the first few days, rose slightly and zigzagged down. It will be seen that the closed circuit pressure remained 1.15 about after twenty days.

The curve in Fig. 25 is the average pressure of the cells at the end of each day. It was mentioned above that one feature of all batteries is; accumulators are subject to the same; that they fall with work and rise again with rest. This is particularly true of the Le Clanché cell and of the dry type variety. It will be seen that the pressure at the end of the first day was rather under 1.3 volts, and that it fell very much in the same manner and that it was still over 1 volt after ten days, though it fell very rapidly afterwards. This type of cell was able to furnish a current of say 1 ampere at least for for ten days without falling below a pressure of 1 volt, so that if 6 volt half watt lamps had been employed the 6 cells would have been able to furnish 12 candlepower for the six hours and for ten days.

Now we come to another part of the problem. A little back the present writer had a long argument with a large firm of makers of dry cells in the United States on this very point that he is working out in these articles. The makers of the dry cells very properly pointed out that with cells of a certain size it was no use adding them in series if current of a certain strength was required; the course that should be adopted would be to connect them in parallel, as electrical engineers call it, on the lines mentioned below.

Taking the tests on the Blue Bell cell as a starting point, it will be easy to see how cells of larger working capacity can be provided for. Merely doubling the height of the cells, making them 12 inches high instead of 6 inches, will double their working capacity, the quantity of current that they can be depended upon to furnish for say six hours a day for a certain number of days and it will also halve the internal resistance. Fig. 26 is a curve showing the effect upon the capacity in ampere hours of increasing the height of the 2½ inch diam-

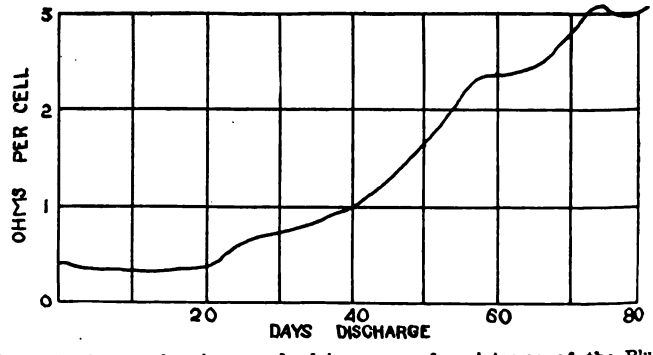

Fig. 22—Curve showing gradual increase of resistance of the Blue Bell dry cells under test.

eter cell from 6 to 12 inches by successive inches. Fig. 27 shows the effect upon the resistance. Another method of increasing the capacity of the cell is by increasing its diameter; and Fig. 28 shows the increased capacity of cells each 12 inches high, and ranging from 2½ inch diameter up to 6 inch diameter by successive half inches. Fig. 29 is a curve showing the effect of the increased diameter of the cells 12 inches high upon their resistance.

It will be seen that by increasing the height and increasing the diameter of the cell practically any conditions that may be required can be obtained. The capacity of the 6 by 2½ inch cell, it will be

Digitized by Google

remembered, was at least ten days furnishing a current of 1 ampere for six hours. In the writer's experience with cells of the Le Clanché type, he has found that increasing the size of the cells increases their staying power in a very much greater proportion than the difference in size. Where the larger cell is worked to its full capacity the staying power would probably be simply in proportion to the difference in size; but where the current taken from the larger cell is smaller in proportion than the test current taken from the smaller cell, the writer believes that the staying power would be very much increased. He estimates for instance that the staying power of the cells that he shows below would furnish the necessary current for the lamps required by a motor car; as it is below what they could furnish on the basis of the Blue Bell cell mentioned above, and that they would furnish that current for at least three weeks, possibly for a month. This means that the changes of the cells would be comparatively infrequent. The writer takes it that it would not be a serious matter to a motor car owner to change his cells say once a month. At the present time probably the cost of the large cells that would be required for the work would be high, but so also is the cost of the complicated arrangement that the cells would displace; and the use of the cells would so simplify the whole arrangement and neutralize so much apparatus to look after that the writer suggests it would be worth a little more outlay. In addition, as is well known, once there is a demand for a particular thing, and particularly in America where there is a genius for designing machinery that will turn out very large quantities of any object that is required, the cost of the cells would probably be considerably reduced.

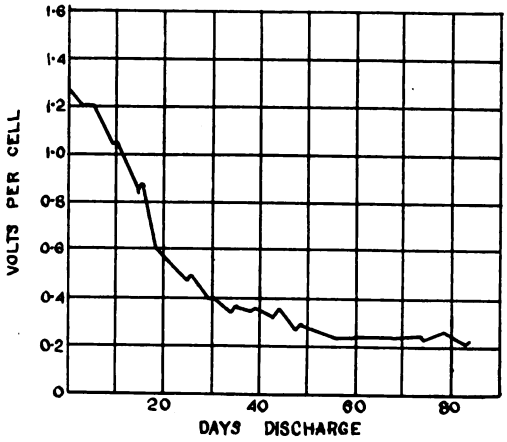

Fig. 23—Curve showing the gradual fall in the pressure of the Blue Bell cells under test, the cells being disconnected when pressure test was taken.

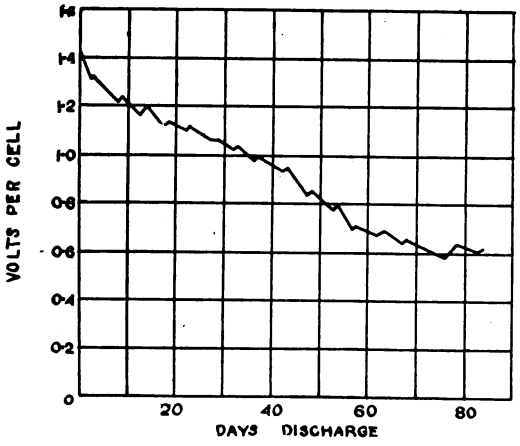

Fig. 24—Curve showing the gradual fall of pressure in the Blue Bell cells at end of each run; the cells being disconnected when pressure test was taken.

And now we come to a point that is partly dealt with above, viz., the effect of the resistance of the cells themselves upon the current actually furnished to the lamps. The resistance of the cells necessitates a larger number being required to furnish a given current. The writer makes out that the following would be the requirements of an ordinary motor car under the present conditions, for the one watt lamps at present in use. Two headlights, each of 6 candlepower, and each taking 1 ampere; four lamps for side, tail and dashboard, taking together 1 ampere. The lamps would be arranged to furnish their light when a pressure of 6 volts was delivered to their terminals. The combined resistance of the lamps themselves, the writer makes out, would be 2 ohms. He makes out by calculation that 12 cells would be required, and he takes it that they could be depended upon to furnish a pressure of 1.2 volts each before renewal. The resistance of the largest size cells shown in the curves in Figs. 28 and 29 would be .1 per cell, so that their combined resistance would be 1.2.

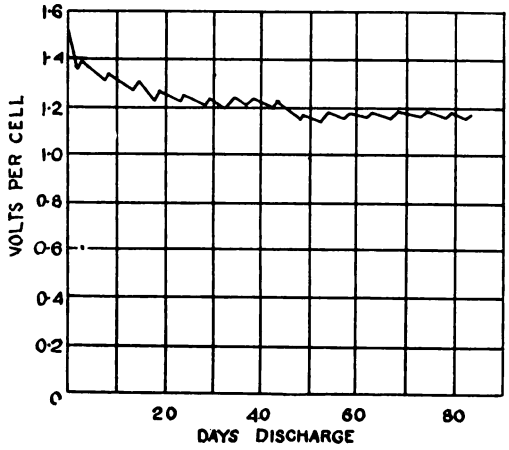

Fig. 25—Curve showing fall of pressure of Blue Bell cells, the cells being connected in series and to the resistance when test was taken.

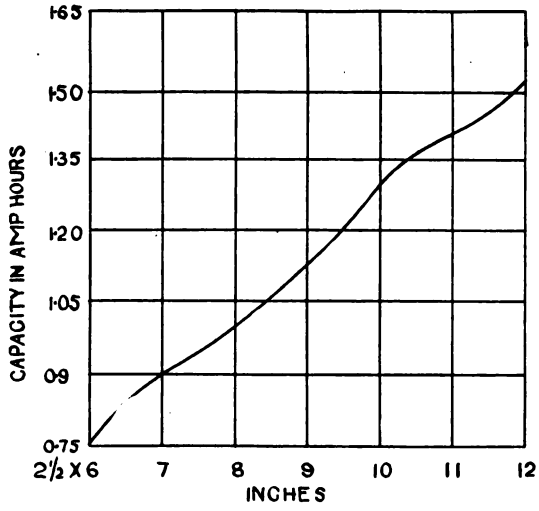

Fig. 26—Curve showing the increase in the capacity of a dry cell 2½ in. in diameter, as its height is increased from 6 to 12 in.

It will be noted from the curve shown in Fig. 28 that the capacity of these cells for six hours per day,

Digitized by Google

based upon the tests of the Blue Bell cell, is 8.7 amperes. It is more than probable therefore that they would last out their full month, and possibly longer.

Another point occurs here that has to be taken account of, viz., whether the large cells mentioned above, 6 inch diameter should be employed, or a

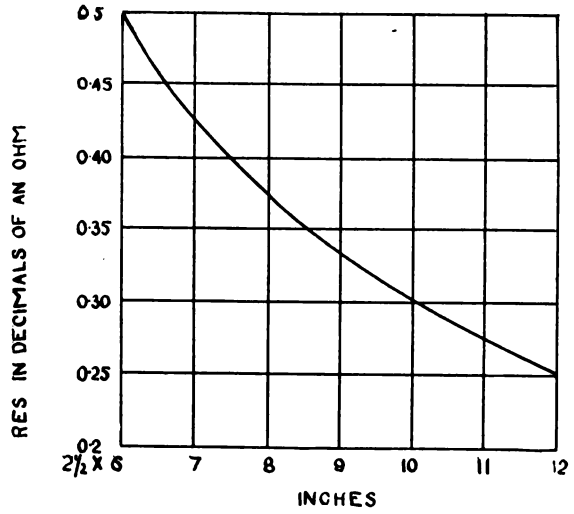

Fig. 27—Curve showing how the internal resistance of a dry cell 2½" in diameter decreases as its height is increased from 6 to 12".

larger number of smaller sized cells. The writer strongly urges that the larger cells should be employed. There are two principal reasons for this. It is well known that in work of this kind, making up battery cells, and similar work, it is the labor that makes the heavy cost. The labor for instance of making a 6 inch cell would be very little more than of making a 2½ inch cell; and once machines had been designed to turn out all the parts of 6 inch cells, and to put them together, the cost of making them, labor and machine, would be very little above that of the 2½ inch cell. The material of course

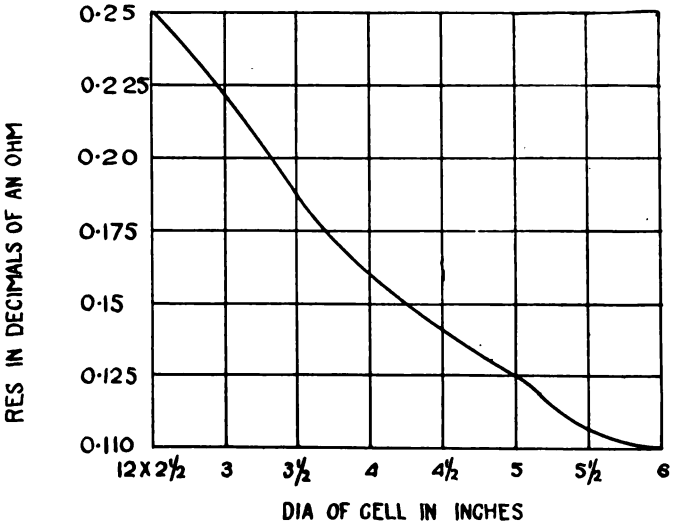

Fig. 28—Curve showing how the capacity in ampere hours of a dry cell 12" high increases, as its diameter is increased from 2½ to 6".

would be in strict proportion to their size, but again the cost of the zinc cylinders which forms a large proportion of the cost of the cell would not increase in the same ratio as the size of the cell. A cylinder whose diameter is double the capacity, double the sectional area, does not contain double the quantity of zinc so that the cost of the zinc would be relatively smaller. As the size of the cells increased it would be necessary to use a thicker zinc plate to form the cylinders out of; but again the relative cost would not be increased in the proportion to the ability of the cell to furnish current. The carbon also would not be in the same proportion as the size of the cell, and there would be one terminal screw for each carbon and one wire to solder on to each zinc cylinder against the number of terminals for the number of smaller cells and the number of zinc wires.

There are also two more serious objections. One is the greater complication in the matter of connections when cells are arranged in parallel, as electrical engineers call it. Fig. 30, three sets of 12 cells each connected in parallel. The number of extra connections will be noted. For connecting cells in parallel it is necessary that each series shall be connected together as shown in Fig. 15, and then the separate series shall be connected together, the end carbons and the end zinc as shown in Fig. 30. Where the cells are sent out in battery boxes ready connected,

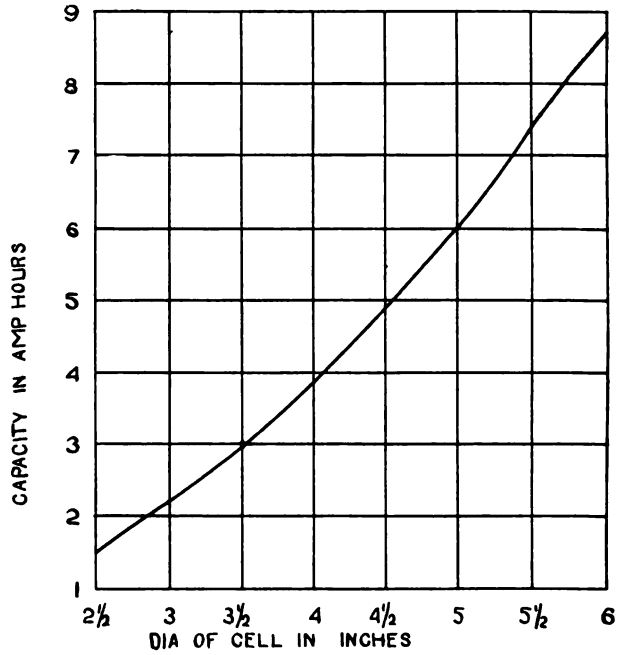

Fig. 29—Curve showing how the internal resistance of a dry cell 12" high deceases, as its diameter is increased from 2½ to 12".

as is shown by the battery company mentioned in the previous part of the article, it is perhaps not of much consequence, but if the question of disconnecting any of the cells arose, and of re-connecting them, a motor car driver might find some difficulty.

The other objection is a far more serious one, and it affects the staying power of the cells very considerably. When batteries of cells are connected in parallel, it is assumed that each series has exactly the same pressure between its end terminals as all the others, and therefore the pressures at the carbon ends and at the zinc ends balance one another, no current passing through any of the cells except when the outer circuit is complete, when the lamps are in use. In practice it is found that individual cells are never alike and that any series of cells connected together are never alike. In manufactured articles there are so many of what mathematicians call "independent variables." A slight difference in the carbon of one of the cells, in the quantity of oxide of manganese or of crushed carbon in one of them, in the rolling or the burning of the zinc of one of

Digitized by Google

them, in the sectional area of the connecting wire, in the resistance of the soldered connection to the zinc, will cause a difference in the pressure of individual cells, and in their resistance. Unless the individual cells are all exactly alike in pressure and in resistance, and unless each series is exactly alike in pressure and resistance, there will be a small difference of pressure between different parallels, and the result will be that a small current will be passing through the cells when no current is passing outside. It will be remembered that while the cells say are

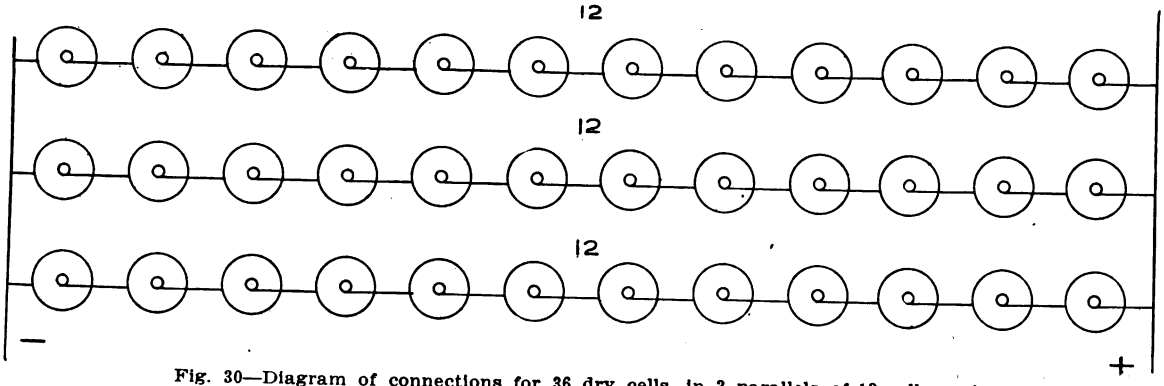

Fig. 30—Diagram of connections for 36 dry cells, in 3 parallels of 12 cells each.

doing useful work for from four to six hours a day, these secondary currents will be flowing for the whole of the twenty-four hours, and though the currents flowing are small, experience has shown that the cells connected in parallel tend to work down very much more quickly than cells in series.

END.

THE AUTOMOBILE ROUND TABLE.

Some News and Views and Pointers for Car Owners and Repair Men.

From G. D. Crain, Jr., Kentucky.—The garage proprietor who has his repair shop on the second floor, as many members of the trade have, often regrets that this fact prevents him from using a pit for the inspection of the under-side of the automobiles which require attention of that kind. True, he might build a box of some sort in which the mechanic could stand, but unless the height of the first floor was considerable there would be danger of accident on account of the projection.

A simple and satisfactory substitute for the pit is in use in some garages, consisting, briefly, of a seesaw device carrying a frame or track on which it is possible to roll the car. After it is run up the incline, its weight swings the frame to a horizontal position, and hinged supports at the end are then let down to hold it in position. The top of the fulcrum of the seesaw, and consequently the entire frame, is about three feet from the floor, and this, added to the amount of road clearance afforded by the car, enables the mechanic to get under and make the inspection without much difficulty, though he must still stoop to some extent. But the arrangement is so far superior to the plan of lying down on the floor, and operating from this awkward position, that it is certainly to be recommended for garages where it is not possible or convenient to provide pits.

In the garage where the device was first seen by the writer, it was found that it took up a good deal of room, though as it was frequently in use this was not a serious objection. However, this condition could be remedied rather easily by hinging the frame at the center, and allowing one section to fold back over the other when not in use. Thus just half the usual amount of space would be needed, and the "pit" could be shoved back out of the way until it was wanted, when it would be the work of only a moment to get it in position.

Study the Instruction Book.

The veteran automobilist who buys a new car sometimes assumes that he knows it all, and that he can take hold of the new machine and operate it without any trouble at all. Of course, this is true in a measure, as far as driving it is concerned, and the ordinary features of supplying oil, water and gas are naturally well understood. But this does not mean that the motorist can afford not to get all of the features of the car well in mind. There are bound to be differences in design that it is well to understand, and many of them may be so important that ignorance of the proper way to deal with them may be extremely costly. The conclusion that one reaches is that the manufacturer's instruction book, though much of it is written for the tyro who has never owned a car before, is important enough to justify careful study on the part of the new owner, no matter how many other automobiles he may have driven in his time.

This is especially true if the owner is changing, say, from a car without starting and lighting devices, and with ignition supplied by a magneto, to one with a starting-lighting-ignition unit introducing battery and other elements with which he has not been familiar. It is like starting all over again, and it is well worth while to give concentrated attention to getting all of these features straightened out, mentally, so that they can be dealt with in the concrete effectively.

One owner recently found, on studying his instruction book, that the universal joint of his new car must be oiled separately, the regular oiling system not taking care of this. It is necessary to supply about a pint of oil every 1,000 miles. If he had not happened to notice this in the book, it might have been overlooked altogether, especially as the car had not been bought from a local dealer.

Competition and Courtesy.

It pays to be polite, always, and it is politic to be courteous, even though you may have all of the business "sewed up."

It is not only humiliating, but rather funny, from the outside, to have to change one's policy in this regard all of a sudden because dangerous competi-

Digitized by Google

tion has entered and has made it seem necessary to "play" to the owner.

Not long ago a new tire and supply house entered a town where one company had had things its own way for a long while. The head of the latter concern is a fine, likable fellow, but his business had grown rapidly, and he couldn't be blamed for feeling and acting a little chesty over his success. Besides, not all of his employes were under his immediate supervision all of the time, and the result was that most of those in the organization acted as though they were doing motorists a favor when they gave them attention, even though the company got good iron dollars for all the material and service supplied.

The new concern went after the business aggressively. It offered more tire service than had ever been available without charge before, and it put in a stock of accessories and supplies that proved very attractive to the rank and file of the owners. Pretty soon it had eaten quite a large hole into the business of the original house, and the head of the latter, who is a good business man, started in to fight for the trade.

Everybody in the concern was given specific instructions about waiting on car owners, and courtesy and politeness were explained on business, rather than ethical grounds. The result was that employes, who were really loyal to the house and wanted to see it hold its position of leadership, were as "sweet as sugar" to those who had any dealings with it.

By this and other methods, the concern will probably hold its own hereafter in competition with the newcomer; but, as suggested, it ought to be rather irritating to the head of the supply house to realize that it took competition to awaken him to the necessity of supplying courteous treatment and polite attention to his customers.

A Discount on Labor Items.

A garage man who found it necessary to devise some methods of improving collections has adopted the plan of allowing a 2 per cent. discount on all labor items charged against the customer, if paid within ten days after the rendering of the bill. The discount is not large, but on a bill of any considerable size it constitutes a sufficient inducement to justify the customer in making a point of paying the bill at the time indicated. The same concern uses a plan which is in more or less general use, that of sending a memorandum giving a full description of the work done the day after it has been completed. Then at the end of the month the regular bill merely indicates the dates when the service was rendered. This insures the customer having a complete list of all of the items for which he was charged. and anticipates any complaints that he is being billed for service which he did not receive. Unless the memorandum is sent out promptly, the motorist may easily forget such things, and hence use of the plan is sure to save a lot of friction in handling accounts.

Watch Your Battery.

One of the most annoying troubles to which the motorist may be subject is a run-down battery. Yet it is, at the same time, one that is as easy as any to avoid. The requirement is simply giving attention to the condition of the battery, on the one hand, and not using current from it unnecessarily, on the other. The man who keeps his battery well supplied with water, and who watches his ammeter to see that the battery is being charged most of the time, is not likely to have much trouble. The motorist who is most frequently in need of battery recharging is the one who doesn't get a very big mileage, but who makes many stops and starts. For this reason such an owner would do well not to stop his motor if he is to be out of the car for only a minute or two, as the power required for starting the engine is so considerable, as a rule, that it takes a lot of running to replace this loss.

Wasting current in lights that are not needed is another way to hasten the complete discharge of the battery. Some drivers have their headlights turned on, if city ordinances do not hinder this practice, even on a brilliantly lighted street, not only irritating other motorists, but creating dangerous conditions for pedestrians, while they are likewise burning up "juice" that may be badly needed later on for cranking purposes.

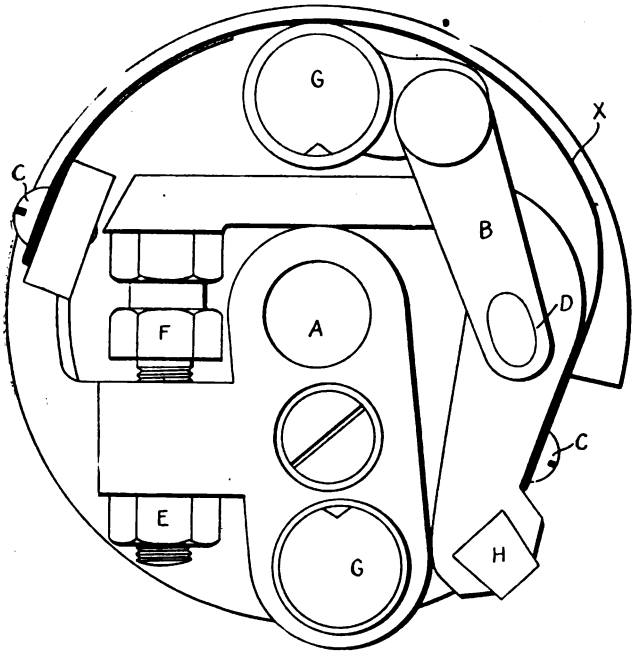
The battery proposition, in short, calls mostly for common sense and ordinary good judgment, and if these are in evidence the owner will have a minimum of trouble.

MAGNETO CONSTRUCTION.

Outline of the Contact Breaker Mechanism of the Dual Type.

The majority of owners hesitate to attempt to correct magneto troubles other than those of a simple nature because of the instructions of the manufacturer. Instead of being an instrument of mystery the magneto is very simple. The writer ran across what proved to be a puzzling case for the owner and other automobilists who attempted to assist the motorist in trouble. The car was a 1915 model Maxwell and was equipped with the Simms-Huff lighting and starting system and the Simms dual magneto. Although the motor starter rotated the crankshaft the motor would not start either on the magneto or the batteries and the last named tested 20 amperes.

The location of the magneto on the car is such that the operation of the circuit breaker mechanism could not be readily seen, but by using a small mirror the parts were illuminated. The movable lever or arm H, shown in the drawing, was frozen and naturally the primary circuit was not established or broken. For the benefit of those not familiar with the operation of magnetos it is explained that the lever H carries a fixed platinum screw which is normally held in contact with the movable contact point on the screw F by the spring X. When the fibre block H, contacts with cams, it is moved inward, as is the lever, causing the points to separate. Contact is re-established when the block H passes by the cam.



The movable lever is pivotally mounted at the point D. There is a small steel stud which rests in a fibre bushing in the movable lever. This bushing is a snug fit to prevent lateral motion, and if moisture or oil reaches the fibre it swells, causing the lever or arm to stick. In the case referred to by the writer the car had been left for a couple of days in a shed near the salt water and during the time it rained considerably.

When the movable lever sticks—it should move freely and easily—it will be necessary to disassemble the breaker box. Remove the dust cap, and at the point A, will be noted a small hexagonal nut.

Digitized by Google

This is part of a long screw which retains the contact breaker to the armature shaft. Use the wrench accompanying the magneto and take out the screw. This will allow the breaker to be drawn out. In replacing it, it can go on but one way as there is a slot cut in it.

With the breaker removed, slip the spring B, to one side. Next displace the screws CC, which provide the tension for the spring. The movable arm can be then pulled off. The maker of the magneto

Magneto Mechanism.

recommends using a small reamer, but in lieu of this can be used the finest of emery paper, rolling it up in the shape of a reamer. Be careful not to remove too much of the fibre bush else lateral play will result. The best method is to make a slight cut, then try the movement of the arm. Do not use any oil whatsoever on the stud or the bush. In reassembling, reverse the order and when the parts are all together test the action of the lever by pushing the fibre block inward. In using the wrench in tightening the screw holding the circuit breaker in place, it is well to exercise care, for should the tool slip the brushes GG are likely to be broken or the springs bent. After replacing the parts, have some one turn the motor over by hand and note the action of the contact points. When correcting a magneto fault of this kind it is well to examine the condition of the platinum contact points and if they be pitted, true them. To adjust the points, loosen the lock nut E and turn nut F to the right to decrease the space and in the opposite direction to increase the gap. Use the gauge if good results are to be expected.

DRY CELLS.

Something in Relation to Their Construction and Wiring.

From C. P. Shattuck, M. E., Rhode Island.—Motorists employing dry cells for ignition, lighting small lamps and for operating horns and other electrical devices, have viewed with alarm the steady rise in the retail price. The increase in price is stated to be due to the inability to secure manganese owing to the war. Manganese is utilized as the depolarizer, it surrounding the carbon rod or post in the center of the cell. As the cost of a cell has practically advanced 40 per cent. it behooves the automobilist to give his set of batteries the care and attention making for maximum service. Much of the failure to obtain full value from dry cells is due to faulty installation and lack of attention.

A brief description of a cell will be of value in conforming to the suggestions contained herein for their care. It consists of a zinc shell to which is soldered a terminal. This shell is protected by a wrapper of heavy paper or cardboard which is flush with the top of the shell. All types of cells are round, but some are placed in square boxes. Although the wrapper is tough it will not withstand rough usage, and if there be movement of the cells within the battery box, the paper will chafe through, causing the zinc of one shell to contact with the other. This contact may be only momentary but it will be sufficient to cause trouble. This is illustrated at Fig. 2, A, which shows an installation of batteries in a metal tool box having a compartment for the cells. Cells 4 and 5 have been rubbing against each other, destroying the protective paper, and the zinc are in contact. Another condition frequently existing where cells are hurriedly and carelessly installed is illustrated by cells 2 and 3. Here the terminals, which project beyond the periphery of the shell, are making contact. Still another fault is shown by cell 1, the negative terminal of which is touching the metal side of the battery box. The drawing also shows how it is possible for the leads from the battery box to become short-circuited by the insulation becoming chafed through vibration. With any of these faults the owner will experience trouble, and sometimes it will puzzle him to locate it, especially if the contacts are only established when the car is traversing rough roads.

The sketch at B shows how the cells should be arranged, and as may be noted, none of the zinc terminals have an opportunity to come in contact with the metal of the battery box. Of course if the

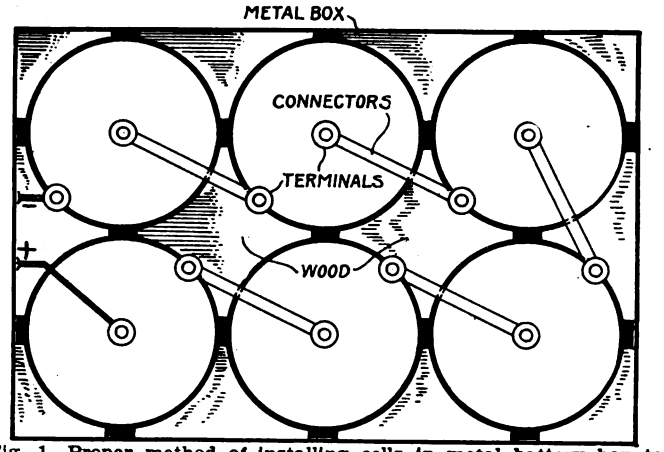


Fig. 1—Proper method of installing cells in metal battery box to prevent short circuits.

box be lined with wood, no trouble of this nature will be experienced, but many owners have converted the all metal tool box into a battery container. If an all metal box be used, or even a lined one, it is a good plan to fit a fibre or porcelain tube for the leads to pass through. These are inexpensive and can be easily fitted by drilling the opening larger and making a drive fit. Both sections of the positive and negative lead should be taped separately, then together, where they pass through the insulator.

Many owners are content with stuffing old paper

Digitized by Google

between the cells and the box to prevent movement. A much better method, and one recommended by the manufacturers of dry cells, is to have some wooden blocks turned to the shape shown at Fig. 1. These will not only prevent movement of the cells but prevent their contacting with one another. All of these suggestions may appear to call for unnecessary work but in view of the high cost of cells it is warranted.

Poor contacts at the connections and attemtping to utilize one or more old cells with new ones are responsible for inefficiency. If plain connectors are employed the terminals should be set up snugly with pliers and gone over again in a day or so. In setting up the terminals on the zinc post do not exert too much energy as the threaded post is only soldered to the shell. If unfortunate enough to separate a terminal from the shell, it can be re-attached by a drop of solder. In testing cells for amperage, do not keep the instrument in circuit but a second. If a cell reads less than six amperes (some designate eight) discard it and replace with a cell of practically the same reading as the good ones. Old and new cells are not practical because the low reading batteries set up a considerable resistance. Always use one make of cells together as it is not practical to wire two or three different types. A very high reading cell does not always indicate long life. A poorly constructed cell can be made to read high by using a strong electrolyte.

In view of the high prices it is best to connect dry cells in series-multiple. For example: If one employs six dry cells in the ignition system, purchase 12 and connect them as above stated. Assuming that the cost is double it is estimated that the service obtained will be greatly increased. This is due to the fact that the discharge rate of a cell is governed entirely by its power of depolarization. Most depolarizers are sluggish in action, and the lower the discharge rate the longer the cell will endure. Another advantage in wiring in series-multiple is that each cell of the set is called upon to supply a

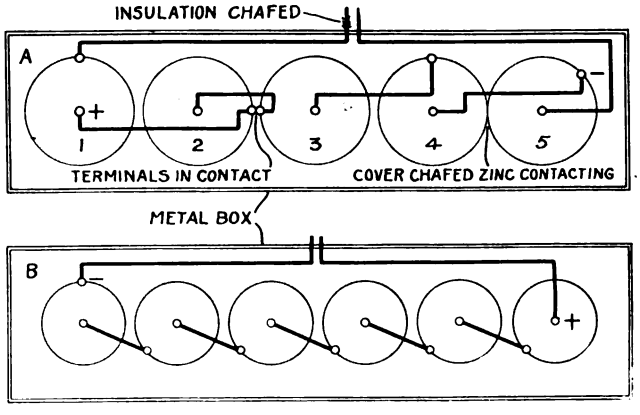

Fig. 2—Right and wrong way to install dry cells. A, careless installation. B, proper method.

relatively small amount of the total current consumed.

It is a simple matter to connect cells in series-multiple. A study of the wiring plans at Fig. 3 will enable the reader to connect cells according to requirements. The sketch at A shows six cells wired in parallel; that is, the zincs are connected together and the carbons. Such a wiring will obtain amperage and in the case illustrated it will be six times that of a single cell, but the voltage will be that of a single cell. To obtain voltage the cells are wired in series, as shown at B. Here the unlike poles of neighboring cells are connected together; for example, the zinc of one battery is wired to the carbon of the next. The voltage will be six times that of a single cell. The amperage will be that of a single cell.

The sketch at C shows 12 cells wired in series-multiple. It consists as may be noted of three sets of four cells, each set being wired in series. This arrangement will leave three free zinc posts on one side and a like number of carbons on the other. By

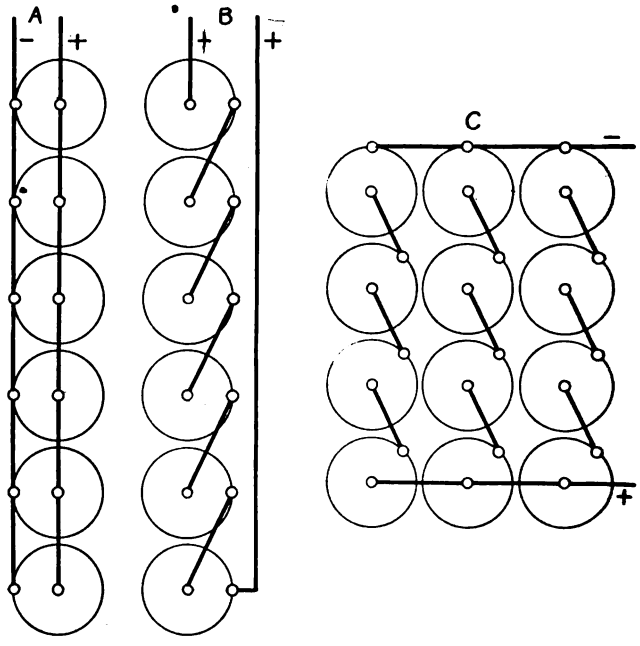

Fig. 3—How to wire dry cells. A, parallel to obtain amperage; B, series to secure voltage; C, series multiple to obtain economy.

connecting the zincs by wire and the carbons in a similar manner the series-multiple is obtained. It is a simple matter to determine the voltage and amperage of any number of cells wired in this manner. The voltage will be that of a single series. Assuming that each cell in the sketch is 1½ volts, four wired in series will obtain six volts. The amperage of each group being 20, three groups will afford 60. Assuming that this be true, 12 cells are more economical than six which afford but 20 amperes. True, the first cost is greater but the investment is warranted in these days of the high cost of dry cells. And it is not unlikely that the retail price will again advance in the near future.

Ohio Operators' Association.

The object of this association which has headquarters in Cleveland, is to improve the conditions of chauffeurs and to win public approval and co-operation. Four hundred members are now registered upon the charter of this association, each member paying the admission fee of two dollars, when five hundred have jointed the charter will be closed and the admission fee advanced to five dollars, there will be a charge of fifty cents per month to active members. The association employment bureau will supply instructors to accompany new drivers of cars who have received the preliminary lessons from company instructors. Unfortunate accidents due to lack of knowledge of properly controlling a car under various conditions may thus be reduced and the commonly accepted rules of the road more thoroughly learned by this association plan.

TROUBLE-DEPARTMENT

This department is intended as a "trouble clearing house" for car owners, dealers and repairmen. Inquiries in relation to marine motors will likewise be answered as they are of interest to car owners and others who use the two-stroke cycle engine.

Readers are requested to make criticism and comments or to freely discuss any subject of interest to the automobile industry, and to add information of their own experience in remedying troubles.

Inquirers are asked to give the fullest information in every case so that replies may be made intelligently, and thus be of interest not only to the inquirer but to others.

1707 Driving Laws.

From F. Straub, New York.—1—Please let me know, in your next issue, if under the laws of this State, any other person or relative to owner of a car, can drive his car, and if so, who assumes the responsibility for accidents, etc., should such person drive his car, owner being in car or not. 2—I also wish to know if such person, except owner, can drive his car in the State of New Jersey.

Reply.—1—The owner of a car can permit any one he pleases to drive his car so long as he does not operate it for hire or the car is not used for other than pleasure purposes. Owners, as well as operators, are civilly liable for damages, while operators only are liable criminally. 2—Under present arrangements of comity, cars from the State of New York are allowed to be operated in New Jersey for a limited time, and New Jersey cars similarly are allowed to be operated in New York so long as the laws of the State wherein registered are observed, but in case of accident the fact that neither the owner of the car or his paid chauffeur was not operating it would materially increase the responsibility of the owner and might increase the amount of the fine or the length of the sentence imposed upon conviction for infraction of the law.

1708 Lubrication Trouble.

From John H. Davis, Indiana.—I have some trouble with an Oakland car, about the oil sight feed. It fills up and overflows and does not feed back to the engine. I have taken the oil tubes off and they are not clogged up. If you know a remedy for it, publish it in next month's magazine.

Reply.—Pressure leaking past the piston rings probably prevents the oil from running back. If such is the case a standpipe of say ½-inch brass pipe tapped into the crankcase and extending upwards 8 inches or so, its open end covered by brass gauze should remedy the difficulty.

1709 Spark Plugs Leak.

From F. C. Humphrey, Texas.—I have a Maxwell runabout, model about 1909, which runs well for a car of that vintage, but I cannot keep the compression from leaking out past the spark plugs. I cannot screw plugs (standard ½ inch) in tight enough to prevent leaking. The threads were rough in one of the holes so I had it tapped out deeper, but that does not stop the leak, and the plug screws down so far that the heat breaks the porcelains about as fast as I can change plugs. I would like to tap the holes for A. L. A. M. plugs, if practical, so I could tighten up on gaskets, but I can find no pipe taps (⅞ inch diameter, 18 pitch thread) of that size listed in any of my catalogues. I don't think there is room to ream out and put in a bushing. Please advise me how to fix it.

Reply.—One-half inch standard pipe taps give a tapered thread which corresponds to the taper of the thread of the spark plug body. If the top of the thread is burned off, broken or corroded, there is bound to be a leak of pressure between the plug itself and the tapped hole. Such being the case your only remedy will be to order some plugs from some spark plug manufacturer, with extra size of thread, and tap the spark plug holes sufficiently large to receive them, or purchase adapter bushings of extra size thread, which will permit the use of metric size plugs. You have not sufficient metal to tap for S. A. E. standard, ⅞ inch, 18 threads to the inch, and even if you did this standard is straight and not taper like a pipe thread, and there would have to be a flat surface true with the thread, against which to screw the shoulder of the plug with a gasket between in order to prevent leakage. It is the leakage of hot gas past the spark plug body which overheats it, this extra heat communicating with the porcelain insulator causing it to break, rather than permitting the plug to extend too far into the explosion chamber on account of the extra size of the tapped hole.

1710 Platinum Points Trouble.

From J. Buickrood, New Jersey.—I have a Ford 1913 model to repair. It has a K.W. master vibrator. The platinum points give out when the car is run about ten miles, and this occurs as often as I replace them. I am not only at a loss as to what causes this, but also as to why it should occur almost invariably when the car has run ten miles. Can you help me out?

Reply.—Our reply to Harold D. Roberts, Oregon, should interest you. There is no doubt that the condenser connections are defective. In other words, the condenser does not prevent sparks at the contact points, which soon burn them up.

1711 An Auxiliary Carburetor.

From H. W., Rhode Island.—A few days ago something was brought to my notice that I want some more light on and thought I would write to you. I saw on a large Locomobile car a tank, and was told it was a Hawxhurst auxiliary carburetor, that it was filled with water and this water was turned to a spray and was injected into the manifold and here mixed with the gasoline vapor, the object being to keep the cylinders from carbonizing. It also helped the power. Can you give me any information on this subject? Is it a fact that this moisture keeps the carbon from forming in the cylinders, and does it help the power? The man who showed this creation to me said it was made in California, that the car used to be taken down every 1,000 miles and carbon scraped out, but since having the article put on the car that it had been 18,000 miles and was clean when taken down. This would prove it to be a good thing on this particular car. Now I own an Overland car, 1914 vintage. In your opinion would it be a good thing for my car? If it worked well on

Digitized by Google

one car would it not work on another? Do you know anything about this method or this particular one? I know by experience, having owned automobiles for twelve years, that carbon in the cylinders spells trouble, and if this method would relieve me of some of that trouble I want to try it. Before doing so I want to hear from someone who knows.

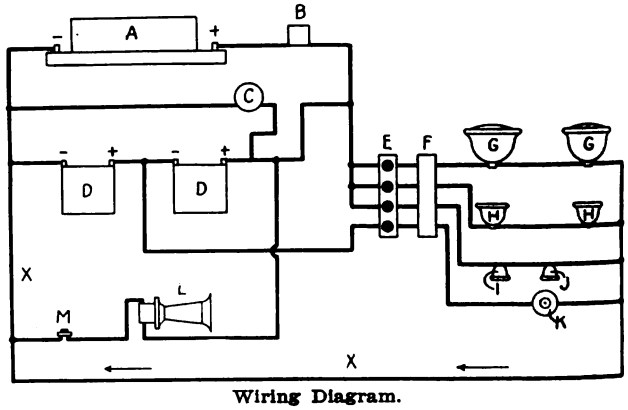
Reply.—Your inquiry is not an unusual one from readers who fail to appreciate that we should not for obvious reasons condemn or recommend any device which may or may not be advertised in our columns. Water has long been used in connection with gasoline and kerosene in stationary gas engine practice. Its mission has been two-fold, to soften carbon deposits and to prevent preignition by increasing the length of the duration of the combustion. Stationary engines employing water are of the slow speed type, and when equipped for auxiliary water supply the ignition can be set considerably earlier, and added power results. Frankly, we have never made any experiments with water, such as you describe. If too much water is used it would interfere with ignition. Water taken into the cylinders of a cold motor would hardly aid starting. If the Locomobile had to have carbon removed every 1,000 miles there was something radically wrong with its operator. Manufacturers and salesmen who have meritorious devices and apparatus should be willing, at least until sufficiently well introduced to be recognized as such, to put their product out on a definite guarantee agreement. If you have any doubts as to the efficacy of this particular device you can figuratively be "From Missouri." Its use could not do any injury to your motor, and if it interfered with ignition you could easily observe it and disconnect it.

1712 Coal Oil in the Cylinders.

From W. N., Cleveland, Ohio.—A good many automobile owners and drivers occasionally use a little coal oil in their cylinders, claiming that it serves to cut the carbon and keep the valves clean. Will you kindly advise in your next issue if you think that this does the work and whether by any possibility it could do any damage to the motor.

Reply.—Coal oil, or kerosene as more commonly called, is more or less efficacious in cutting carbon deposits. We do not know how it could affect a motor as you seem to fear it might.

1713 Carbon Trouble.



From William A. Butler, Rhode Island.—I have an Overland car, 1916, model No. 83, and it seems to carbon up about every 1,000 miles so that it absolutely refuses to climb hills, even of very slight grade. I use S. O. Co. gasoline and Polarine oil. I keep the level about ¾ full instead of full as the instruction book says, and I run about 80 miles to the quart of oil. I have tried carbon removers, kerosene, denatured alcohol, and have put the same in the cylinders after each day's run, while the cylinders were hot, and I cannot get but a slight increase in the mileage before the engine is full again. The car has been run about 2,300 miles and I have had the carbon burnt out and valves ground once and now it is full again.

I have been told by a friend to put a small piece of camphor in on top of each of the pistons and run the car as usual, his argument being that the camphor kept the carbon from forming in cakes on the inside walls of the cylinders and top of the pistons, and also kept the cylinders bright and clean. Will you kindly advise if there is anything in this scheme that would be a benefit to the motor or if it would be harmful? Also will you advise if there is anything I can do more, to help this trouble?

Reply.—It is our opinion that you have been running with a very rich and uneconomical mixture, due to improper carburetor adjustment. The result is, probably, that the piston rings are stuck in their grooves, thus causing the inordinate consumption of oil. We do not believe you will be able to get your car to run satisfactorily until the pistons are removed and the piston rings loosened in the slots. If you have this work done, and then find that your spark plugs accumulate oil after a short run try an oil of heavier consistency. If the camphor treatment were to prove efficient the demand would soon boost the market for this commodity. Local treatment such as is proposed to you, will not take the place of a necessary major operation. It would be like trying to reduce a fracture by the application of a liniment. Do not forget that a too rich mixture, more gasoline than is necessary, costs money, reduces the power and causes serious trouble in the motor itself. The moral should be obvious—use as little gasoline as possible. It is abuse to use too much.

1714 Diagram for Lighting.

From E. Z. Adams, Louisiana.—Will you kindly give me a wiring diagram of the lights on my auto-

Wiring Diagram.

mobile. It has two headlights, two sides lights, a speedometer light, an electric horn, dome light and tail light. These lights are run from two storage batteries and the two batteries are charged from a Vesta generator. There is also an ammeter, a four-way switch and a horn button. Could you give me an idea how to wire this up on a four-way switch, so that one button would light one headlight, another button the other headlight, the third button the two side lights and another button the tail light. Also to show when the battery is being charged or discharged through the ammeter. I have tried to figure this out myself, but with my limited knowledge of electricity I could not do it. I would certainly appreciate it if you can help me out on this.

Reply.—You probably did not realize how much of a job your request would entail, to tell you all we can concerning automobile lighting, especially as we have no means of knowing whether the system to be employed is the double or single wire, nor the voltage of the lamps and type of switch, as well as the magnetic relay and fuse block. Our advice to you is to employ some capable electrician to lay out

Digitized by Google

the circuits and perform the actual work, your confessedly limited lack of knowledge rendering it more than likely that you would make an unsafe and dangerous installation, possibly ruining your battery and generator, even if you do not burn up your car from accidental short circuits. We are, however, as requested, giving you a diagram which employs 6-volt lamps exclusively, three circuits having two lamps in series, the fourth using but one-half the battery voltage to operate the single dome light. Of course if you desire to have this fourth circuit contain two lights you would have the voltage 12, same as of the other three, arranging the two lights in series. You must remember that this layout is only one of a large number that could be made. We do not claim anything great for it except that the lamps may be all of the same voltage. If the voltage of the generator is but 6, it would not be practicable at all, except the two storage battery containers were wired in parallel, and a separate and distinct circuit were established for each lamp.

In the illustration, A represents a 12-volt generator, B a magnetic or centrifugal circuit breaker to prevent discharge of the storage battery through the generator winding when the voltage of the current generated is less than that of the storage battery, or when the generator is at rest, C is the ammeter, DD the storage battery, E the four-contact switch, F the fuse block, GG the headlights, HH the side lights, I the tail light, J the speedometer light, also acting as a telltale light for the tail light, K the dome light, L the horn and M the horn push button. Arrows show the direction of flow, while XX show the common return from the lighting and horn circuits.

1715 **His Car Stalls.**

From S. C. Adams, Massachusetts.—I have a Ford 1914 car, and would like you to answer through your magazine, why it stalls with the gas lever on the third notch of the quadrant. It runs on first and second notch, and if I jump it from second to fourth it runs, but put it on third and it stops.

Reply.—There are three possible reasons why the motor will stop when the throttle lever is advanced to the third notch, while operating on both second and fourth. The least probable of the three is that in this position the primary ignition circuit is either short circuited as would occur if the carburetor throttle lever or rod should touch some bare spot in the primary wiring. The other two causes would be too rich or too poor a mixture at the troublesome position of the throttle lever. This you should be able to determine, for by your carburetor needle valve control you should be able to increase and decrease the amount of gasoline. If increasing it by turning to the left keeps the motor running it conclusively proves the mixture to be too poor, while conversely if shutting off a part of the gasoline by turning it to the left keeps the motor running it proves too rich a mixture. It matters not whether your motor has a Kingston or Holly carburetor, to correct this condition you should raise the float, or lower it, the former if the mixture is too poor and the latter if too rich.

1716 **Will Not Stay in Gear.**

From Henry Trolio, Mississippi.—I have a 1912 E. M. F. 30 touring car which a few days ago got so that it would not stay in high gear. On examination it was found that the bolts in the radius rods where they are connected to the frame of the car were loose and allowed a good deal of play in the rear wheels. My repairman fixed this and said that it would be all right, but it continues to jump out of high gear. Can you tell me the cause? He says that the gears are in first class condition.

Reply.—The loosening of the bolts may have been the result of poor alignment of the two shafts within the gear box, which in turn causes the jumping out of high gear. You will probably have to have the gear box bushings renewed and the transmission shaft lined up with the crankshaft. If the driving shaft has not been sprung or bent this should remedy the difficulty.

1717 **Battery Inquiries.**

From George Taylor, Maine.—My present car is a Reo the Fifth. The headlights are 15 c.p. and small tail lights, dry cell ignition and magneto. I have the Gray & Davis lighting and starting system. 1—My battery, I suppose, is a 6-volt, marked L. B. A. What make is it? 2—The battery tests by a volt meter, 6-2. The hand on the ampere meter on the dash used to point to 0 in the center, when the engine was stopped. Now it goes over about 1½ amperes on the discharge side. Does it keep on going over if the battery goes down? 3—How far would it have to go before it ought to be recharged? 4—When the engine is running, the ampere meter registers about 5 on the charge side. Can you tell by voltmeter at what degrees it would freeze or would I have to have a hydrometer? 5—Is there any safe arrangement that you know of that I could get to recharge at home from the common house lights?

Reply.—1—The battery is manufactured by the Willard Storage Battery Co., Cleveland, Ohio. 2—The ammeter shows the amount of current going into or coming out of the storage battery. If your lights are switched off and the generator is not running the indicator should be at zero. If, however, the automatic cut out, which normally prevents the battery from discharging through the generator, is not functioning properly it will soon ruin it. It is possible that your ammeter may be out. You can tell whether the battery is discharging through the generator by temporarily disconnecting the wire from the generator. If the needle does not change position it shows that the ammeter is out. From this you will note that the ammeter could not indicate the condition of the battery. 3—If you are using more current than you are putting into the battery you will soon ruin it. 4—The voltage remains fairly constant until almost totally discharged or in such condition as to demand expensive replacements. For this reason the voltage should not be depended upon. Use a hydrometer. 5—We do not think you should consider such an installation. The generator on your car is the proper method of recharging, and if working properly should keep the battery fully charged. We advise you to write the Willard Storage Battery Co. for their full and complete instructions for the care of storage batteries, read and believe what they say and do not attempt any experiments unless you are prepared to buy a new battery. If kept fully recharged they will not freeze unless the temperature goes considerably below zero. If fully discharged they will quickly

Digitized by Google

freeze, which should not do any more harm than already done.

1718 **Magneto "Goes Dead."**

From J. Bell, Maine.—My car is a Maxwell, model I, of 1911 make. The engine is started by four dry cells, and runs on a low tension Splitdorf magneto. Here is the trouble. The magneto will work perfectly for a while and then go dead, and I have to use the dry cells. Perhaps then the magneto will work perfectly for 100 or more miles and then go dead. The speed of the engine or the temperature seem to make no difference. Repairmen are unable to locate the trouble. I have put new points on the magneto, the coil is in perfect shape and there are no loose or broken wires. The trouble seems quite blind. The ground wire is all right and the car operates perfectly on the dry battery. Please locate the trouble.

Reply.—The fact that the magneto will generate current only part of the time, while the battery ignition is dependable, proves conclusively that there is an occasional short circuit within the magneto itself. The current is generated in the armature winding, picked up by a so-called collector ring and conducted to one pole of the make-and-break mechanism. If a short circuit is completed at this collector ring or in the winding of the armature by oil carrying small particles of carbon there will be the same effect as would be produced by switching to the "off" position, which opens the battery circuit and short circuits the magneto circuit. The magneto should be cleaned by some one who really knows how, else there will be danger of demagnetizing the magnets when the armature is removed. Our advice is that you send the magneto to the nearest service station of the Splitdorf Electrical Co., or such people as the Holzer-Cabot Co., Boston, for an overhaul.

1719 **Largely Curiosity Queries.**

From Horace P. Nichols, Connecticut.—I would like some information regarding dry cells. 1—Supposing 4 dry cells are reduced to 20 amperes and one wishes to strengthen the current by adding four 20 ampere cells, multiple series of four cells each. Will this increase their voltage and would there be a loss of current on the 30 ampere cells? 2—Also in working a 6-volt lamp, what would be the advantage or opposite result of this connection of 20 and 30 ampere battery with dry cells? 3—I have put in two gas cocks in the tube connecting with the gas tank (Presto) drilling one for a 2-way connection, and another connected with a hole drilled in the side to the manifold, to be used in starting in cold weather. Now, can any harm result by using too rich a mixture, other than waste of gas? 4—Would enough current of gas to supply one ½ foot burner be about the proper amount of gas to let on? If this rig works all O. K. it makes a check ring, 2 cocks, 20 cents, 3 feet tubing, 18 cents, connected with manifold with solderless union 10 cents. 5—I would like any information in regard to connecting up dry cells of different amperage. 6—Also what would be the effect of grounding the current of 4 dry cells through the magneto of a Ford car? This was done by mistake, and I wonder whether it has injured the magneto. 7—If not, how much current can be thus used without injuring the magneto, and how can the amount of injury be determined? 8—How can it be ascertained whether the magneto of a Ford is up to what it should be? 9—Will ammeters and voltmeters indicate and what should they indicate?

Reply.—1—Four dry cells connected in series would give the same voltage as several hundred cells connected in multiples of four in series. In like manner a single dry cell as big as a barn would show the same voltage as one used for a pocket flashlight. The amperage of the two multiples of four would be much more, consequently the actual current consumption would therefore be less out of each cell, and they would last longer than if each series were used alternately. 2—Longer life. 3—Not from using too rich a mixture, but from using too much of the proper mixture you may blow out a cylinder head. 4—You can get several times as much as you need providing you let it run into the cylinders long enough. Our advice is not to attempt any amateur acetylene starting experiments unless you have positive means for measuring the amount of each explosive charge. 5—The strength of a chain is only that of its weakest link. A battery of dry cells has only the amperage of the weakest cell when connected in series or as a chain. In multiple-series the amperage would be the total of the weakest cell in each series. 6—Ruin your battery and probably demagnetize the magnets of the magneto. 7—None at all without danger of injury. 8—If it furnishes sufficient voltage to light the usual 6-volt lamps in series of two, and also to operate the ignition, it is proof positive. 9—If the voltage is up to standard, the amperage should not matter, as ammeters show not the amount of current being generated at a certain voltage, but the amount being used. As we have previously advised you, voltage is the strength or intensity of the current. The quantity of the flow of electric current can only be measured by knowing the voltage and amperage, their product being the actual quantity, expressed in units of watt-hours. For instance, a rectangular plot is 40 ft. long and 20 ft. wide. Its area is 800 sq. ft. Again a 6-volt current is flowing at 20 amperes per hour, equivalent to 120 watts per hour. If the voltage were 12, and the ampere hour flow 20, the equivalent would be 240 watt hours.

1720 **Engine Stops.**

From Walter Evans, Indiana.—I have been working on an Overland car, 1914 model, with a Splitdorf magneto, model A. The engine will stop dead, also sometimes it will not start. I have traced the trouble right to the coil. I was called to this car and it was dead and had stopped when running, and there was no electric current at the breaker nor at the coil connection. All I did to start it again was to take hold of the ground connection and pull it backward and forward and it started right from compression and the engine ran O. K. You can take this coil off and connect it with other wires and away from the engine and magneto and it will play the same trick once in a while without moving the switch, coil or wires, and when it works it throws a good blue spark at the high tension wire, and no blue spark at the primary contact. It seems to make no difference whether it is on the magneto or battery current.

Reply.—Probably a defective switch which occasionally gets short circuited or a connection jars loose. If you will persist in trying the coil to see how long a spark you can pull you had better order

Digitized by Google

another to have it in reserve. Coils are not designed nor constructed to stand such abuse. You should not get any spark when breaking the primary current. The condenser is used to prevent it.

1721 **Spark and Coils.**

From Ewing McLean, Indiana.—1—A spark advance of from 30 to 35 degrees is generally provided for, but how many degrees from the dead center of the retard should be provided for? 2—How are coils boiled out? Are they baked out in an oven or boiled out in oil or paraffin of some kind? 3—In repairing coils we find some filled with common sealing wax, some with paraffin and some with a black, sticky compound similar to ozite. Which is the best? 4—Has anyone experimented in using a water-cooled engine as an air-cooled one, by making water jackets to the air inlet of the carburetor?

Reply—1—For running, not any. For starting, no more than absolutely necessary to start the car safely. 2—Never heard of such an operation as "boiling out coils." The K-W Ignition Co. heat them in a vacuum chamber, exhausting the moisture as it is driven off by the heat, and when thoroughly dried out the impregnation compound is admitted to the chamber. 3—That which contains the least moisture and the highest dielectric properties is the best. 4—Probably. Our advice is that you do not make the experiment unless you use some one else's motor, as it would soon ruin it.

1722 **Hard to Start.**

From J. H. Mills, Jr., Texas.—Seeing that you help so many others in their troubles, perhaps you can help me. I have a Ford that has been run 6,000 miles. It runs perfectly but was hard to start at first and has been getting worse in this respect until now it has to be cranked 25 to 30 times to get the first explosion. Then it will run one or two revolutions and stop. When cranked again it will start immediately and run 3 or 4 revolutions and stop. Each time it is cranked it will run a little longer than the last time until it will finally run all right. After it finally gets started it runs perfectly, does not miss and has plenty of power. The compression is extra good. The spark coils are new K-W coils put on about a month ago. I have no master vibrator. The vibrators buzz every time the timer makes contact, so it is not caused by the points sticking. The carburetor is a Holley and has been recently cleaned. The gasoline stands about half full in the well in the carburetor, which is as the makers say it should. The spark plugs are in perfect condition. The commutator is clean and perfectly oiled and the commutator wires are new. The spark plug gaps are 1/3[illegible] inch, which is, according to the K-W instructions, with the coils. I have always used good oil and it has never been down to the lower gauge or above the upper one since the car has been from the makers. I get 25 to 30 miles per gallon but I open up the needle valve about ¼ turn to start. If the car did not run so perfectly after it is finally started I would think there was something seriously wrong with it. but I have been unable to find the cause of the hard starting, and if you can give me any suggestions I will greatly appreciate it.

Reply.—Looks very much as if your gas was too rich when starting, as a result of a leaking gasoline inlet needle valve in the carburetor, although lowering the level of gasoline in the carburetor should make starting easy. The fact that you neglect to give the date of model leads us to think it may not be of recent make, consequently an early model of Holley carburetor. If this is the case try a later model, one that will handle the hard-to-vaporize gasoline of to-day more effectually. In Texas one should expect a car to start more easily than in higher latitude. You should have your carburetor so adjusted that the needle valve will be open the same amount when starting as for ordinary running. The float level adjustment should care for starting and needle valve opening should regulate the amount of fuel for usual operation. If you try and adjust the carburetor fuel supply for various throttle positions you are not getting all that you should out of it.

1723 **Radiator Types.**

From John J. Martell, Michigan.—1—Is a vertical tube radiator more efficient than a honeycomb? I mean, will it cool the engine better than a honeycomb? 2—Which will get the least damage from freezing? 3—In which of these radiators are leaks easier repaired? 4—Will a honeycomb clog easier than a vertical tube radiator? 5—Which radiator would you advise me to purchase, a honeycomb or a vertical tube? 6—Where could I get a radiator tha[illegible] the outer shell would be seamless? I mean the sides and top. 7—Give me the address of some radiator manufacturers that make radiators for Ford cars. My car is a 1915 model Ford.

Reply.—1—The honeycomb type of radiator is usually considered more efficient and it is more expensive to construct. It is, as a rule, used on the higher priced cars. 2 and 3—We are inclined to think likewise that the honeycomb radiator would be rather more difficult to repair in case of a leak although there are several different styles of construction of both the honeycomb and the tubular types. 4—No. 5 and 6—You must govern yourself in the purchase of a radiator by the replies to your previous questions. 7—The Candler Radiator Co., 1086 East Jefferson Ave., Detroit, Mich., and the Auto Sheet Metal Works, 1532 Michigan Ave., Chicago.

1724 **Horsepower Queries.**

From F. Dave Moran, Colorado.—1—I would like to know how to test a stationary gas engine in order to determine the horsepower at a given number of R.P.M. I have a 4 horsepower gas engine, of 450 R. P. M., and am sure it is not developing the horsepower and would like to know how to test the same, as it is a new engine in first-class shape, as valves, compression and ignition are concerned. 2—The difference between or the percentage an 8 horsepower gas engine will develop against 8 horses, or please compare an 8 horsepower gas engine with the power of 8 horses. 3—Please explain to me why a steam engine of 10 horsepower will develop more horsepower than a 10 horsepower gas engine, at the same number of R. P. M., on the same test, and how much more horsepower will it develop and steam more than gas. 4—Also please tell me how to test the horsepower of a gas tractor on the draw bar or the belt or pulley.

Reply.—1—Rating the horsepower of gas engines is frequently a matter of conscience on the part of the manufacturer. If properly designed and constructed a four-stroke-cycle stationary gas engine should develop a mean effective pressure of 67 pounds per square inch against each piston. This 67 pounds multiplied by the length of the stroke ex-

Digitized by Google

pressed in feet, this by the area of a cross section of the piston or bore of the cylinder expressed in square inches, multiplied by the number of explosions per minute and this total divided by 33,000 will give the developed horsepower that one should expect. Thus a single-cylinder four-stroke-cycle engine 5 inches bore and 6 inches stroke, at 450 revolutions per minute, should develop $67 \times 6/12 \times (5 \times 5 \times .7854) \times 225 \div 33{,}000 = 4.48$ horsepower. Just what your engine develops can only be told by means of a Prony brake, dynamometer or some similar device. 2—An 8 horsepower engine that will really develop 8 horsepower has sufficient power to raise 33,000 pounds 8 feet in one minute. This standard horsepower was established as about the average amount of work that an average horse would perform per minute during ten hours. 3—The ratings of steam and gas engines are purely nominal. A gas engine is more likely to be overrated than a steam engine and a steam engine can usually be operated at a higher steam pressure and longer cut off, using much more steam as a result, and thus develop more than the rated horsepower. 4—We do not know nor do we know of any one who knows.

1725 **Lubricating Oils.**

From Lincoln Riley, Nebraska.—1—In the October issue in answer to No. 1689 you say "Ford cars should not use light oil. Use medium or heavy." Is this statement correct and when was the discovery made? The Ford people are strong in recommending only light oil for use at all times. 2—Also I would like to know if Polarine is made in more than one grade? A dealer told me that it comes in light, medium and heavy, but I have only seen the one kind which seems to be about medium.

Reply.—1—Reference was made to Ford cars that have been in use for some time, the bearings being worn, when it was stated in our October issue that light oil should not be used. 2—There are at least two grades of Polarine oil, medium and heavy, and quite likely there is a light grade also.

1726 **Recharging Batteries.**

From R. B. Ireland, Louisiana.—I come to you for a little information in regard to charging storage batteries from a direct current. Now we have here a direct current of 220 volts. How many lights of 16 candlepower (carbon) lights would I have to use to reduce it low enough for charging batteries? As we have a number of carbon lights here which are available they are no longer used for lighting. Any other information which you can give me in regard to charging storage batteries from direct current will be appreciated.

Reply.—Were we to devote a column or two to reply to your inquiry, we would not be able to give you nearly so complete information for the care and recharging of your storage battery as you could get from the printed instructions which any storage battery manufacturer will be glad to mail you on request. Charging storage batteries from a 220-volt current is possible, but unless one knows a good deal about electricity it might be a rather dangerous operation and expensive to replace possibly ruined batteries. Were we to tell you just how to proceed and you were not to follow instructions absolutely and get into trouble as a result, we would probably be blamed. In this case we advise you to secure the services of some capable electrician to install the necessary bank of lamps and instruct you in the operation of recharging, etc.

1727 **Tire Chains.**

From Emil Miller, South Dakota.—I will be greatly obliged if you will answer the following questions through the columns of your valuable paper: 1—When driving a car in the mud and using zigzag chains on the front wheels, is it best to use a chain on each wheel or just on one front wheel? 2—When using chains on both front wheels, does it have a tendency to draw the front wheels together. or crowd if the wheels are otherwise in line. 3—Which do you consider the best chain for mud, a zigzag or a straight cross chain?

Reply.—1—Both wheels. 2—No. 3—Straight cross chains for mud. For ice, probably zigzag chain.

1728 **A Motor Knock.**

From S. H. Showalter, West Virginia.—I would like information regarding a pounding knock in the motor of my model T, 1913 Ford car. It sounds like a crankshaft main bearing knock, but it is not, as I have examined all the bearings thoroughly two or three times and they all fit tight enough.

Reply.—The knocking you refer to usually indicates loose bearings somewhere, especially if these knockings are heard when traveling over rough roads, and regardless of speed or spark lever position. However, engine knocks are likewise due to carbon deposit and something wrong in the mixture, and sometimes to a leaking of water-logged carburetor float.

Experience with a Buick Car.

From Walt Von Seggern, Wisconsin.—I have a model 10, 1910 Buick car. Have owned it three years and have driven about 5,000 miles each season over hard roads. It has two speeds and I have often driven three and four miles on low speed without changing. I use Stearn cylinder oil in the transmission and rear axle, and I think it the best. I tried to use air-cooled gas engine oil in the crankcase, because it was heavy, but I had to clean the exhaust valves every 200 miles so I stopped using that. I am using the heaviest oil I can get now from dealers, and I haven't cleaned or ground the valves for about 1,000 miles. I don't add oil to that in the crankcase any more. I fill it, which means one gallon, and run about 200 miles, then drain out what is left and fill with new oil. It pays on this car to do so. The bearings wear too fast otherwise. I do everything myself except if there is any lathe work or blacksmithing. When I can't vulcanize my tires with my little Marvel I discard them.

I am a steam hoisting engineer and I guess that helped me when I started driving and caring for my own car. I am using the Remy type S magneto, and a one-inch, model L Schebler carburetor. The old model D would only run in hot weather. The car runs good and is quiet. Maybe I can get along for four or five years yet, but I expect the cylinders will need regrinding and new pistons. I fitted new rings on the old ones some time ago. The bearings and axles on the rear end have been removed twice since the car was new. If the bearings are loose on the lower end and the differential gear, you can expect broken or stripped gears. I haven't had any bother with the transmission and hope I never will. It works just right.

Digitized by Google

Need of Air Filters.

From Charles E. Duryea, Pennsylvania.—On pages 62 and 67 of your September issue I find some very interesting mentions of the dust and grit we expose our auto engines to and then wonder why we get no better results. "Carbon" is a common complaint and many things are taken to cure the trouble. Yet as Mr. Stratford truly pointed out, "large percentages of road dust" are to be found in what is called "carbon." What you say about the accumulation of dirt and dust in the dust pan is correct, but if it gets into the dust pan it certainly gets into the carburetor inlet and so into the cylinders. Is it any wonder that piston and rings wear out rapidly? This constant supply of grit is reason enough for overheating because it makes the walls of the cylinder rough when we all try to get them smooth. It reduces power first by friction and later by leaks. There is absolutely no excuse for it. What is the answer? Easy. Some sort of air filter. Years ago a few makers fitted cloth screens to the carburetor inlet but the average driver took them off at the first cleaning day and they never went back. Now that we know more and need better things let us hope the air filter will stay before the public and be regarded as necessary as a starter or a magneto.

Engines for Motor Boats.

From A. J. Applegate, Kansas.—In recent issues of your publication I find you have advised two different subscribers that it is impracticable, if not impossible, to have an automobile engine work satisfactorily in a motor boat. I wish to state that for the last 4 years I have had installed in a 16-foot Racine motor boat a 20 horsepower automobile engine giving perfect satisfaction. It holds seven people easily, has a three-blade, 14-inch propeller with a 26 degree pitch, as I remember. I can get 15 miles per hour out of this, which is sufficient to easily beat any boat on the river, so I have never tried to run it any faster. It has a regular automobile outfit equipment, including gear pump, exhaust covered with asbestos rope, and muffler under the seat in the rear, discharging the exhaust above water, and the pump takes water in from one side of the bottom of the boat, makes a circuit of the engine, and also exhausts under the bottom of the boat, making the engine absolutely cool at all times. I have arranged to this an improvement on the Atwater-Kent distributing system for ignition. The flywheel is just back of the front seat underneath, and is the only awkward proposition about it, that I must raise the front seat (which is hinged) apply the handle, start the engine and then lower the seat for the passengers. I steer this with a cord running around inside of the boat so it can be steered from any part of the boat, making it a one-man proposition. I worked out this plan without any pattern or other assistance.

The sub-frame is firmly bolted to the interior of the boat and the engine is held in place with four long bolts passing through the sub-frame and headed through steel plates on the bottom of the boat, which being drawn tight holds the engine perfectly rigid. This boat is perfectly dependable, starts at any time easier than most automobiles, can maintain almost any rate of speed within its limit, can be throttled down so it barely moves through the water, or starts ahead, taking up its speed almost immediately if the occasion requires.

I could arrange a starter on this engine, which with the other accessories that I have would, as far as I can ascertain, from reading the Motor Boat and other publications, give me as good a boat as anyone would wish, and I would be glad to answer any questions about this to the end of contradicting the statements that have been frequently made that an automobile engine cannot be successfully installed in a motor boat, because I have known other instances where such installations have been perfectly satisfactory.

I had the usual two-horsepower, two-part, two-cycle engine in this boat when I purchased it and so have all the other boats around here, and I have cranked a solid hour in a vain endeavor to get the engine started or I would go down to the boat and it would start off with a touch. I have had this engine stop absolutely still, five miles from the boat house and no possible persuasion would make it go, and this experience is that of all the other boats on the river, and I made up my mind that I did not want any engine like that in my boat, so I took it out and installed in its place the engine described above, which starts and stops exactly as I want it, and I have read accounts of high power boats whose engines refused to start even in racing, when thousands of dollars were at stake, so I say an automobile engine perfectly installed is superior to anything I have discovered in marine engines.

Reply.—In case anyone wishes to consult Mr. Applegate, his address is Wichita, Kansas. Although this publication is devoted to motor cars and not motor boats, we still believe it is not advisable to use automobile motors in motor boats. The requirements of running an automobile and of running a motor boat are decidedly different, and with this idea in view, the construction of the engines widely varies as regards strength and speed for rated horsepower and in other respects. That an automobile motor can be applied to a motor boat is demonstrated by Mr. Applegate's experience, but this by no means proves that it is advisable to do so. We are afraid, likewise, that those who have had extended experience with motor boats would be somewhat sceptical that a 16-foot Racine boat could make 15 miles per hour. However, we gladly publish Mr. Applegate's letter, and if any reader desires to equip their motor boat with an automobile rather than a marine motor, he will do well to consult him.

Ignition Trouble of Mr. Brown.

From Carl F. Gentner, Oregon.—I would like to offer a few suggestions in regard to the ignition and the troubles of the Ford cars. I have owned and repaired them ever since they were put on the market and I find invariably that very nearly all the trouble is in the oil which is used in them. In regard to the ignition trouble of John A. Brown, of Rhode Island, with his high tension Bosch magneto, I believe if it is set right he should have no trouble with a light oil. The trouble with the Ford car starting all lies in its multiple disk clutch which drags when being turned over, as does the flywheel which rotates in oil, and troubles especially if too heavy oil is used. I notice he says after the car is started, there is no trouble with it the rest of the day. I find a very quick flop is all that is required and they seldom if ever kick back if given the quick turn. I leave my car out all night, and with a good priming it

Digitized by Google

starts off all O. K. I would not be troubled with all the coil and timer troubles on a Ford car again for one. Just try a high grade light oil, and see if your troubles are not eliminated. Valvoline is what I use. I enjoy reading your magazine and would like to hear from more Ford car owners.

Carburetor and Cold Weather.

From Chas. A. Rawstrom, New Jersey.—If it would interest you, I learned something last week about my car which I have run for three years and never found out before. I have generally had a little trouble running in cold weather, but last week I could not get it to hit on all cylinders no matter how I tried. The spark was fine, there was plenty of gas and all adjustments as usual, still a lot of skipping and jerking. A friend said, "Have you shut off your air since the cold weather came on?" No, I had never thought of it. Well, after I had more than half, almost ¾ closed the air inlet to the carburetor, it ran like a top.

He Has No Trouble.

From J. H. Clare, Kentucky.—I have a two-passenger runabout Schacht car, made in Cincinnati, Ohio, that I have run for six years and have not had any trouble with it. I have taken care of it myself. I use Polarine cylinder oil all the time. It is the best oil that I can get. It doesn't carbon like some others. I use coal oil in the differential, once in a while. It makes my car run mighty nice. I keep all nuts tight and all connections tight and right and I have no trouble.

Remedy for Leaking Grease.

From B., New Jersey.—The inquiry of A. J. Morel, No. 1688, brings to mind a remedy for grease leaking out of the axle which I think was published in your journal some time ago and which I think he will find the only remedy for the trouble. It is to bore a ¼-inch hole through the axle casing six to ten inches from the wheel; this he will find effectual. If there is grease enough in the differential to keep it properly lubricated it will eventually follow the shaft to the wheel.

Cure for Cramps.

From F. Lee Rogers, New York.—Referring to No. 1695, of your October number, would say that I think Mr. Harvey E. Harris, of Connecticut, will be able to get great relief from the cramps of which he writes, if he will put extra covers over his feet and limbs on retiring. If he will keep his feet and limbs quite warm during the night, I believe he will not have much trouble with cramps.

The Road for Garage Use.

From J. W. M., Fergus Falls, Minnesota.—The way in which automobile accidents may happen are as numerous as the stars. No matter how careful a driver may be, if a d—d fool is at large, no one is safe.

The other evening about 4 o'clock my wife and I started out for a little drive up to a town called Elizabeth, along one of the most traveled roads leading out of the city. As we were driving along just outside of town, we passed several fires by the roadside where the railroad men, or others, were burning up rubbish by the roadside. There was very little wind and what there was came from the south and the smoke drifted over the road, and naturally, I drove through it. A little way ahead we saw a larger smoke which, apparently, came from the grass on the south of the road, and about twenty rods on the further side, I saw an automobile coming toward us. As I was near the smoke I slowed down and turned slightly to the right as a precaution against the approaching machine, which I thought might meet us in the smoke, not knowing just how wide it extended. As I entered the smoke, which was much denser than I supposed, I jammed into the rear of an automobile in which were four ladies. The owner, I learned after the collision, was out at the side of his engine pouring kerosene through the carburetor to clean it out. My right front wheel struck his left rear wheel and both machines were damaged. Fortunately, no serious injury was sustained by the occupants.

I asked him his reason for stopping in a main traveled road to flush his engine with kerosene, and he said he did not like to do it at the garage as it made so much smoke.

Now, I think that there should be a general, mental test applied to every man who wants to drive an automobile, and all such fools as that should be denied a license. The damage to my machine does not trouble me, as I was so thankful that no person was seriously hurt. The only regret I have is that I did not smash his auto to such an extent that it would be, forever, out of commission; but as I could not have done this without injury to his passengers. I am glad that it was no worse.

I do not know whether this will interest your readers, but feel sure that it was a new kind of an accident. There should be stringent laws to prevent accidents, but what law could make one immune from the acts of such an idiot?

(Note by the Editor.—We have again and again encountered automobiles standing and occupying half or more of the road. Sometimes the driver may be working upon them, and at others the occupants are either enjoying a lunch or a ramble in the fields. Of course, they are totally oblivious of the fact that they have no right whatever to occupy any part of the road for such purpose. The highways cannot lawfully be turned into repair shops or for garage purposes. If a car is to be stopped, it should be left by the roadside and not allowed to take up any part of the road. Many seem to feel that if they occupy but half of the road they are within their rights, but this is not the case. They have no right to use any part of the road for such purposes.)

Weight of Cars.

From R. R. Shepard, California.—Anent your editorial, "Second-Hand Car Prices," it is not singular that high priced cars are offered at a greater per cent. of reduction in price when second-hand than low-priced ones. The reverse should not be the case, because the second-hand-car goes to the man economically minded. The high-priced car is always the heavier. The heavier the car the greater the operating expense: Corollary, Mr. Second Hand Buyer takes that car which may be operated for the lesser expense—and he is wise.

I have offered 75 cents a pound for a one-ton car which shall be worth the money, and can find no manufacturer to satisfy the demand. My first car

Digitized by Google

weighed 1,875 pounds ready for the road. The subsequent cars I have had from the same manufacturer weighed 2,500 pounds ready for the road. The maker now offers me none but a 3,000 pound car ready for the road. The maker and I have parted company, and I have degenerated from a four-cylinder user to a six-cylinder driver in order to get a car of 2,200 pound weight ready for the road. The greatest manufacturer of automobiles in the world to-day has succeeded by reason of the fact that he is furnishing a car of ability without unnecessary weight.

For Noisy Gears.

From Reader, Nevada.—I had a trouble similar to Mr. Revelette of Kansas. It was the same hum of the gears and like his it only came at certain speeds. For a long time I could find no one who could locate it or give me any idea of its cause. I believe with you that the "Buick people" were right, for a competent garage man solved my troubles. He told me that it was in my differential and that he could stop it. Knowing he was a capable man I turned my car over to him and sure enough he fixed it and while doing so he explained to me the fault.

In order to get efficient and silent service the

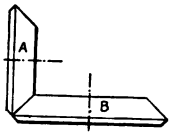


Fig. 1.

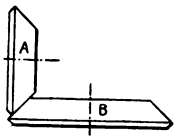

Fig. 2.

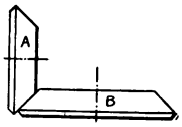

Fig. 3.

gears in the differential must be perfectly adjusted. Some people in assembling the rear of the car do not appreciate the necessity of this question. In taking up the lost motion between the gear of the drive shaft, A, and the differential, B, they either adjust the gear on the drive shaft back until the lost motion is taken up, as in Fig. 2, or they adjust the differential to the drive gear, as in Fig. 3.

Now the only way to obtain silent service is in the right adjustment, as in Fig. 1. Any competent mechanic knows the necessity of this. Not only for silence but for the efficient service of the gears. I think if Mr. Revelette will look at this point he will find his trouble.

For Mr. Gardner of Long Island, I, being a wagon-maker by trade, his trouble sounds to me like a "rim-bound wheel." Tell him to have his wheel examined by a competent wheelwright.

Brake Leaking Grease.

From C. Edner, Colorado.—I have had lots of trouble with my brake leaking grease, but I have now fixed it so it never leaks a drop. The ring that went next to the Timpkin bearings was sprung. I had it in the shop and straightened it and in place of leather washers I cut two washers from an old felt hat and cut a copper washer and put the felt between the two and it doesn't leak a drop. My car is an E. M. F., 1912 model.

"Uses Too Much Oil."

From R. O. Dulaney, Oklahoma.—In your October issue, under No. 1697, "Uses Too Much Oil," if you will advise Mr. Coy P. Smith to put a leather washer in his oil filler cap and after putting in oil, screw the cap down so it will be air tight, his trouble will stop. I had the same trouble with my Maxwell 35 until I read the instruction book that goes with the car and found the trouble to be as I have above stated.

For Leaking Grease.

From H. R. F., California.—Having noticed several subscribers complaining of grease leaking from rear axle housing of their Ford cars, would say I have had some trouble with two Fords and tried everything but met with no success until I applied Perfection grease retainers. Several of my friends are using these and are greatly pleased with them.

OLLA PODRIDA.

Being a Mixture of Practical and Theoretical Automobile Topics.

BY JAMES F. HOBART, M. E.

It happens that I live upon an unpaved, oiled street, which has a single car track in the middle, and which street is used a good deal by motor trucks, particularly large trucks. Naturally I have a good chance to observe motor trucks in action, under all sorts of conditions, and it is safe to state right here and now, that there soon will have to be a big change for the better in operating motor trucks, or there won't be any trucks! Of all the rattling abominations seen upon the streets, these trucks take the "blue ribbon."

Some trucks run over this street which I do not think have had any slack taken out of their connections since they were put out of the factory. Judging by the noise, these trucks must be loaded with "lost motion" principally. If there is a single part of one of them which does not rattle as it goes past, then it is because the other parts make so much noise that the rattle cannot be heard!

A few evenings since, there was a heavy shower coming up; it was nearly dark; the wind was almost cyclonic, when down the street came a noise which completely drowned all sounds of the approaching storm. Three heavy, 3 ton trucks, driven at the highest speed they were capable of making came along, one close behind the other, all making for their home garages, and trying to beat the coming storm. Noise? The two Irishmen were not "in it" when they were awakened during the first night in America by the passing of two fire engines, which were responding to an alarm. Pat rushed to the window, thrust his head out into the noise, saw the thundering smoking vehicles and called to his friend: "Mike! Mike! Come here quick! They're movin' hell and there goes two loads!" Trucks or any other machinery left without adjustment will soon wear out and call for costly renewals, and the problem right now is: "What are we going to do about it?" Owners do not often see their trucks in action. They send them to the service shop as often as seems necessary. Truck drivers (some of them at least) seem oblivious to the need of better care of machine connections. I have heard of garage repairmen who deliberately send out cars with certain nuts left loose so as to make it certain that the machine came quickly back again for more adjustments and repairs.

As things are now, it is of no use to tell truck owners that their property is threshing itself to pieces for lack of proper care and attention. They won't believe any such line of talk. It is breath wasted to talk to the truck drivers. They seem to

Digitized by Google

be more interested in packing a load upon their machine than in keeping it in perfect running condition, and the louder the rattle, the better some of the truck drivers seem to like it! Tell one of them about "taking up lost motion" and he will grin and say nothing. Sometimes it seems as though half the truck drivers were standing in with the repairmen and "shaking down" truck owners to a division of spoils.

The problem resolves itself into one of educating the public until rattling vehicles will not be tolerated in the streets. And it also seems to me that the Automobile Dealer and Repairer will do a great deal of the necessary educational work among truck owners, drivers and users, and the people who must listen to the unnecessary racket some of these trucks constantly make.

Let us then go after noisy trucks at every opportunity. Tell those who should know how the noise should be abated and avoided. educate all concerned to a slight idea of the better service to be obtained from trucks which are so well adjusted and cared for that they are practically noiseless in operation. By so doing, we will be doing good to ourselves and our nerves and aiding a grand industry, which as yet is in its swaddling clothes, at the very beginning of its infancy. Motor trucks of to-day will, ten years later, be viewed with as broad a smile as we give to the little "lunger" which chugs, chugs contentedly past occasionally; odd looking and noisy, but still serviceable and doing its "get-there" stunt seven days in the week. The motor truck of 1930 will be a far different machine from the rattling abomination which we are tolerating to-day, while awaiting progress to something better. But. while waiting, let us keep at everybody concerned, in season and out of season, to make the most of the crude motor trucks we are using to-day, for with proper care and constant attention, they may be separated from two-thirds of their noise-making capacity by simply keeping connections well set up, all nuts well tightened, and parts prevented from becoming loose and rattling against each other. That's just what makes most of the noise. And remember, the trucks of 1930 will have four power wheels instead of two.

Sand Puffing Tires.

Recently, as a large touring car was passing along a sandy road, I noticed a very peculiar action in one of the power wheels. It was a sort of puffing action, and (the car was running very slowly) as every two or three spokes passed, a jet of what seemed to be sand, would spurt upward from between the tire and rim. The action did not take place at the bottom of the wheel, but just above the point where the tire touched the ground and was flattened a bit as the weight of its share of the car came upon the tire.

The action did not seem to be a mere shaking out of sand from between the rim and the tire, for there was none of the action at the upper portion of the wheel, only just a few inches ahead of the bottom part of the wheel, as stated above. Apparently the sand jets spurted up from four or seven inches and I could see both sand and dust as the car rolled past.

What could cause such action, and what effect would it have upon the rim and the tire? Sand cannot be sucked into a wheel and spurted out again, time after time, without some affect upon the wheel, and it is idle to say that such affect could be beneficial.

"Cranky" Automobiles.

Now and then I have noticed a car which seems to steer very badly and to sometimes deviate from its proper course without any apparent movement of the steering wheel. Two such cars chanced to pass in a crowded thoroughfare and a collision was averted by less than an inch between the passing cars. The drivers of the two cars "looked daggers" at each other, but passed without a word. The incident reminded me very forcibly of the cross-eyed man who ran against a pedestrian upon a broad sidewalk. "Why don't you look where you're goin'?" shouted the cross-eyed man. "Why don't you go where you're looking?" retorted the other man. And it is much the same with the two cars which nearly grazed each other. They both ran crooked paths. Like the wagon wheel, which was badly sprung, "it would run out of the track, kill a snake and come back again," as its action was aptly described by a farmer. But these automobiles would vary their courses sometimes, apparently without cause and seemingly quite beyond the control of the drivers.

A few days since I saw one of these "wobbly" cars turn into a garage and being acquainted with the garage owner, I soon found opportunity to look the car over a bit. By standing beside one of the forward wheels, and pressing or pulling against the top thereof, in the direction of the opposite wheel, there apparently was nothing the matter with either of the wheels. They both seemed firmly attached to the axle and to the steering mechanism.

Not being satisfied we jacked up the forward portion of the car, placing two jacks, one just inside each steering knuckle to which each forward wheel was attached, and then, when I tried a wheel, I found something. I could move the top or bottom of that wheel back and forth nearly three inches, and either wheel was equally loose. The cause was found to be in the wear of the connections between the axle and the short steering knuckle.

Very little attention is given to the matter of knuckles by the average garage man, as this part seldom gets "out of kilter." But the knuckles should as surely be looked after as should the engine or the gear case. Many a car driver has come to grief by taking something for granted. Just know that a thing is so or is not so, then you are as safe as it is possible to be.

Don't take anything for granted when you are "tuning" up" your car. In the days of the old "lungers" when 100 miles was a great non-stop endurance run, the writer rode as observer in a car which made the distance with no engine trouble whatever and with a small gasoline consumption. But the car made too many penalized stops. The driving chain jumped off the sprockets twice during the run and that killed the chances of the car for the prize. The point of the matter is this: The driver of the car knew the chain was a little slack and he took chances that the chain would stay on, rather than tighten the chain as he should have done.

Don't take chances with the steering knuckles or anything else pertaining to safe and sane automobile driving. Be sure of things and you won't have trouble. Worn knuckle connections may cause a serious accident when you are not dreaming of trouble. And you have got to look pretty closely at a car, sometimes, in order to find knuckle troubles

Digitized by Google

when they do exist. The writer tried the forward wheels of the machine for a side-swing, but could find none, push as hard as he might, until after the front axle had been jacked up, leaving the front wheels hanging clear and free. Then knuckle trouble showed itself a-plenty.

The reason that the trouble did not reveal itself when pressure was put against one of the forward wheels was that the wheels at that instant happened to be standing so as to brace each other. They were both pulling in at the top and out at the bottom, or the opposite way—out at top and in at the bottom. As long as both wheels stood bracing each other the car could not be swayed sidewise, but had the wheels happened to have been in any other position—one leaning in, the other out, the knuckle looseness would have revealed itself and probably would have been attended to at once.

It is a mighty good thing to jack up both front and rear axles once in a while. It gives you a chance to see what is going on in the knuckles, also in the wheels, and when the rear axle is jacked up, you can get someone to hold one wheel, or you can leave one on the floor, and find out a whole lot regarding the condition of things in the differential by turning one wheel back and forth as far as it will go. Then when both power wheels are clear of the ground, by revolving one wheel and noting the smoothness of that wheel in one direction and the working of the other power wheel in the reverse direction, the "feel" of the gears will sometimes tell a whole lot as to their condition.

Next, let the man at the other wheel do the turning while you let your wheel slide through your hands with just enough pressure placed upon it to make the gears work a bit. The manner in which the wheel moves through your hands, smoothly or "lumpy" will tell whether the gears work well, or whether they are badly worn and "caterpillar" from one tooth to another.

Oil and the Gear Case.

At least once a month the gear case should be "bled" a little, either by opening the drip-cock placed for that purpose, or by removing a screw which will allow a teaspoonful of oil to escape from the gear case. Only a very small quantity of oil need be drawn off, for it is only drawn for the purpose of finding out whether the oil in the case is still fluid or whether it has become so thickened with ground-off metal particles that the oil will stand "straight up."

You never can tell the condition of oil inside the case unless you test it in a manner something as above. When making the test, and no oil comes out when the petcock is opened or the screw is removed, don't jump at the conclusion that the oil has gone bad just because none runs out the instant the case is opened. There may be plenty of good oil in the case and still none may show itself at the opening. The oil may be thickened with dirt or metal dust and no oil can escape until a hole has been dug through the thickened stuff with a wire or a bit of wood.

Test out the gear-boxes in this way and don't neglect to look after them until the oil has become mud and will not flow out when a hole is made in the case. Test out occasionally as above noted and if there is no test hole in the gear-box, then make one forthwith. If a screw already in the case cannot be made to do the trick, perhaps by the hole being drilled clear through into the space inside the box, then drill a hole especially for that purpose and tap the hole for either a petcock or a plain pipe plug. The latter is rather the more desirable, as petcocks clog so readily that one must have a wire run through it before it can be trusted to tell the condition of the oil. But put in a good ¼ inch pipe plug, and when you remove that there will be no doubt whatever regarding the condition of the oil in the gear case. Be sure to make the hole well down to the bottom of the gear case so it will surely come below the level of the oil.

Cold Weather Cars.

Some car owners run their automobiles all winter and seldom have trouble from freezing or in starting. The magneto certainly "has it all over" the dry cell for cold weather starting, for when a dry cell is frozen, or cold enough to freeze, there is little chance of getting current out of it, while the magneto will work at any old temperature, which is not hot enough to drive the magnetism out of the permanent magnets or to destroy the insulation of the armature winding.

If cars are to be used in below zero weather and must stand in that temperature when not running, then means must be taken to keep them thawed out. Storage cells and dry cells as well, will seldom freeze while at work, for the very act of providing electricity keeps them from freezing. If a dry cell be so very cold that you cannot get current out of it, then just get two or more warm cells, couple them in series, and connect them in series with the frozen cells.

The carburetor is another cold weather danger point, as far as starting is concerned. I have seen car drivers who kept an old flatiron, a brick, piece of soapstone, or some other convenient article, upon the stove and when the car was to be started on a cold morning, the hot object was placed beside the carburetor for a short time and the heat imparted to the carburetor and to the gasoline, caused the car to start readily and easily.

There is a way by means of which a carburetor and the dry batteries may be kept warm even in the coldest weather, and by means of a little engineering, the radiator circulation may be protected also. The material required will be a gasoline blow torch of sufficient capacity to operate continuously during the longest period the car is to be left exposed to freezing temperature. By increasing the capacity of the blow torch reservoir it may be made to run for a week without a stop if necessary. Air pressure may be pumped up in the blow torch reservoir by means of the regular tire pump.

A coil of small copper, brass or aluminum tubing will be required, and it should be so attached to the blow torch burner that the products of combustion shall pass through the tube. It will be necessary, therefore, that the diameter of the tube bear a certain relation to its length in order that it may not be so small that the hot products of combustion cannot be driven through the whole length of the tube without the torch "breaking" occasionally.

Carry the tube to and around the carburetor, pass it through the battery box and attach it to the water jacket in such manner that a circulation will be maintained therein and there will be no cold weather trouble for that car.

Automobile Dealer and Repairer

A Magazine of condensed and compact information for busy readers.

Member of the Audit Bureau of Circulations.

PUBLISHED THE MIDDLE OF EACH MONTH BY

THE MOTOR VEHICLE PUBLISHING CO.

71-73 Murray Street, New York

Telephone, {7377 / 7378} Barclay — Post Office Box 654

Entered as second-class matter at the Post Office in New York City.

M. T. RICHARDSON, President and Treasurer — F. R. WHITTEN, Secretary

A. A. HILL, Editor

F. R. WHITTEN, Advertising Manager

E. DAYTON, New England States

H. F. LUDINGTON, Illinois, Indiana, Michigan Wisconsin and the West

F. M. DAMPMAN, New York, New Jersey, Pennsylvania, Ohio

TERMS OF SUBSCRIPTION.

One Copy, One Year, Including Postage.....$1.00
One Copy, Six Months.....60 cents
Single Number.....10 cents
Foreign Subscriptions.....$1.50, or 6s. 3d.

Remittances should be made by Express Money Order, Draft, Post Office Order, or Registered Letter. Foreign remittances, where possible, by International Money Order.

ADVERTISING RATES MADE KNOWN ON APPLICATION.

NEW YORK, NOVEMBER, 1915.

Missing Number.—Our Readers are requested to remember that it always gives us pleasure to re-send numbers which have gone astray in the mails.

The Automobile Dealer and Repairer in Australia and New Zealand.

Mr. R. Hill, Matlock House, Devonport, Auckland, New Zealand, is our accredited representative in Australia and New Zealand for obtaining new subscriptions.

CARELESS MAIL HANDLING.

Although he is held strictly accountable by the subscriber, a publisher is helpless and at the mercy of a power over which he has absolutely no control, when it comes to the correct delivery of his periodical to its destination through the mails. All he can do is to see that it is properly wrapped and addressed, and taken to the post office. There his authority and scrutiny ends.

Yet this ought to be enough, and it is enough in the case of first-class mail. Indeed, the loss of letters in transit is remarkably small and is a decided credit in this respect to the care and efficiency of the post-office department. It proves, however, that correct delivery by mail is possible, and that incorrect delivery is unnecessary.

This indifferent or careless handling of second-class mail can therefore be accounted for in no other way except that it is considered of little importance. But it goes without saying that it is just as important that a paper or magazine as a letter be delivered to the person to whom it is addressed. Nor is it necessary to state that in the majority of cases a magazine is of more value to those who have subscribed to it and paid for it than a letter. The value of the mail has absolutely nothing to do with its correct and safe delivery. All mail should be delivered correctly whether it is worth much or little. This the post-office department has agreed to do, and it can and should fulfill its agreement.

Yet complaints of subscribers failing to receive this magazine reach us by every mail, and the number of such complaints is increasing. The thing that makes it especially unfortunate, not to say exasperating, is that we are absolutely powerless to remedy the situation.

This explanation is made purely in the interest of such readers, and in the hope that if they can suggest a remedy that they will do so. In every instance where the Automobile Dealer and Repairer fails to reach a subscriber another copy will be gladly sent him upon request by a postal card, and in such cases we consider the favor ours and not theirs. We enter into an agreement to deliver the magazine to its subscribers and no trouble or expense will be spared to do it.

Yet it will easily be seen how powerless we are to do this when the fault is with the postal authorities.

SUBSCRIPTION SWINDLERS.

For a year or more there has been a gang of swindlers traveling around the country, chiefly in the West, but to some extent all over the country, soliciting subscriptions for this magazine and other journals and pocketing all the money they get without reporting to the publishers. These rascals are fluent talkers, and have some kind of a premuim for either getting the subscriber on the spot or a promise to have the publisher send him one. In making appointments of agents for soliciting subscriptions, the various publications have heretofore been too indifferent, so that the subscription fraud has been able, without much difficulty, to secure sample copies and in many cases, receipt books. Of course, the prospective subscriber is deceived by these evidences of the party's connection with the publishers and in many cases easily parts with his money.

Collecting money in this way and pocketing it constitutes, if not larceny, at least a breach of trust which would land the solicitor in jail, if he could be caught. Several of the publishers, including ourselves, are on the track of some of these rascals and there is hope of putting them where they belong. We do not wish to say that all solicitors of subscriptions are frauds, by any means; the most of them are men of integrity and are trying to earn an honest living.

It is a good plan to refuse to pay any money to a solicitor who either gives a premium of some sort to subscribers or who promise premiums to be sent by the publishers. Very few publishers are permitting solicitors to give premiums. This paper does not permit any solicitor to give a premium to a subscriber. If the Automobile Dealer and Repairer isn't worth a dollar a year it isn't worth anything.

THE QUESTION OF HORNS.

A correspondent of the New York Times thinks that all harsh, raucous-sounding signals shall be banished by law from automobiles. His contention is that they are often employed to practically order pedestrians out of the way when they have as much right to the streets or highways as the automobiles. Another indictment is the effect of these horns on the nerves of sensitive people. The Times in an editorial commenting on the communication referred to suggests that all signals, loud, mellow or soft, be prohibited by law and the car driver be compelled to proceed with such extreme caution as to reduce accidents to a minimum.

The Times errs in its contention that the sounding of a horn is always equivalent to a peremptory

Digitized by Google

order to get out of the way. It is intended as a warning only, the same as the whistle of a locomotive is designed to warn people of the approach of a train and the whistle is far louder and more nerve-racking than the harshest of automobile signals.

With no means whatever of warning of their approach, automobile accidents would be far more numerous than they now are. How often has it been charged that a driver didn't sound his horn and by reason of his negligence somebody was hurt?

The everyday noises of street traffic in cities, are of such a character that a loud signal is necessary to overcome them. In the country a horn with a penetrating sound is indispensable at intersections of roads and at curves, to warn those approaching diagonally or from the opposite direction. Otherwise collisions would be inevitable.

These observations must not be understood as attempting to excuse reckless driving or injudicious horn sounding, of which there is far too much both in city and country.

WOMEN DRIVERS.

The assertion of a judge of one of the police courts of this city that women are unfit to drive automobiles raised something of a storm of protest, as might have been expected and as it deserved. Quite likely the judge did not exactly "speak before he thought" but he was just a bit hasty in speaking, even as was the psalmist who said in his haste that "all men are liars."

No better evidence is needed that women are fit to drive cars than that they are driving them successfully and in constantly increasing numbers. Indeed, a woman has just driven an automobile clear across the continent, and alone at that. But making the assertion as mildly and as inoffensively as possible, the truth impels us to admit that we never see an automobile coming with a woman driver than a feeling of apprehension arises as to whether we are to have the whole, a part or none of the road.

For it must be reluctantly admitted that the fair sex are often liable to act upon impulse rather than reason, and here is where their driving is often inferior to that of the average male. On the other hand, women are far less liable than men to attempt driving with a brain excited or addled by alcoholic liquors.

The proper driving of an automobile depends upon certain principles, some of which women are more likely and some less likely to have than men. They probably lack in the important qualities of nerve and judgment, but they are superior in quickness of perception.

Meantime, here in New York City many women are driving and as far as can be observed, with the average proficiency.

THE TWO-CYCLE MOTOR.

On another page, Mr. C. E. Duryea, the dean of automobile engineers, asserts that our reply to an inquiry in relation to two-cycle motors "was not fully considered," and that the reason this motor has not "come into its own is owing to prejudice."

But the two-cycle engine did come into its own several years ago and was found wanting. Where, for instance, is the two-cycle Elmore car? Where the two-cycle Knox car? What has become of any of the cars that once used two-cycle motors? Echo answers: "As extinct as the proverbial Dodo." And they were by no means abandoned from prejudice, but because they could not be made to give as good results as four-cycle motors.

After an automobile manufacturer at considerable expense, and based upon favorable conviction, has adopted a certain form of motor, he never discards it unless he is obliged to. If there is any prejudice or pre-judgment formed, it is all in its favor, and no change is likely to be made unless from necessity. Change is expensive.

Like the steam-driven automobile, the two-cycle motor for automobile propulsion has been weighed in the balance and found wanting. "The proof of the pudding is in the eating," and not in the theory. No one can rightly claim that either the steam car or the two-cycle motor has not had a fair show Quite likely most manufacturers who produced or used them now feel that they were given a better show than they deserved. But if this is not sufficient the following testimony should have additional weight:

"Probably the strongest points in favor of the two-cycle type are the lighter flywheel and the absence of valves and valve gear, making this type the most simple in construction and the lightest in weight for its developed power. Yet, for the larger power units, the four-cycle type will no doubt always maintain the standard for efficiency and durability of action."—Gas, Gasoline and Oil Engines, by Gardner D. Hiscox.

"When a two-cycle motor is running without moving the car it will almost always miss explosions. * * * The two-cycle motor has a very limited range of speed and will miss explosions when running very fast or very slow or with the throttle nearly closed. This missing will be impossible to avoid. No form of two-cycle engine is as economical of gasoline as a four-cycle engine."—Modern Motor Car, by H. P. Manly.

"It has been previously stated that the four-cycle motor is almost universally used, and to properly understand the reason for the preponderance of this type over the simpler two-cycle forms it is necessary to compare the actual results obtained from the two-stroke motor in ordinary practice with the advantages a purely theoretical consideration will give it. Trouble is also experienced with the cooling, lubrication, and carburetion groups, as most two-cycle motors have peculiarities which make proper oiling and gas supply difficult. They consume more fuel than the four-cycle engine of the same power and are not so economical as regards use of lubricating oil."—The Modern Gasoline Automobile, by Victor W. Page.

"It is not as efficient or as economical of fuel as the four-cycle engine."—Dyke's Automobile Encyclopedia.

The foregoing is merely a presentation of the evidence pro and con in relation to the two-cycle and the four-cycle type. The reader has heard the testimony. Let him form his own judgment.

CAR STEALING.

Although automobiles are being stolen right and left, little sympathy need be wasted upon the victims. In the days of the horse vehicle, the first thing the owner attended to on arriving at his destination was to hitch the horse.

When the owner of an automobile arrives at his destination, he often takes no precaution whatever

Digitized by Google

to prevent the car from being driven away by some evil-disposed person. Yet the car can be made fast in less time than it requires to hitch the horse.

Automobile stealing has now reached a high state of efficiency. The organization consists of the original thief, the receiver of the goods, the disposer of them, and sundry subordinates, such as the makers of license tags, disguise painters, etc. Yet they can be quickly put out of business if car owners will simply take such measures for the protection of their property as are cheaply provided and easily applied.

REASONS FAVORING SLOW DRIVING.

According to a recent gasoline consumption speed test made by the Automobile Club of America in behalf of the Cadillac Motor Company, fast driving compared with slow burns up gasoline to a greater extent than is usually supposed. The actual figures were as follows:

Speed Miles Per Hour.	Miles Per Gallon.
14.5	20.6
24.5	18.3
33.9	16.3
43.5	13.6
52.9	10.8
62.8	8.8
69.51	7.41

Of course these figures are significant for comparison only. It really makes little difference whether the Cadillac car uses much or little fuel per mile; the main thing is that it uses much more when going at high speed than at low, and so much more that most drivers will be inclined to take the matter into account. The test reveals one more reason for slow driving when fast driving is unnecessary. It should be stated that although the use of lubricants did not show quite the same variation, yet even there the car that is driven rapidly uses much more oil than the one that is driven at a slow speed.

And if the two foregoing reasons for slower driving are not sufficient, two more of equal importance may be added: Fast driving compared with slow is still more expensive and destructive in the matter of tire wear, and the wear of tires is by no means a small item of expense in the running of an automobile. The other reason favoring slow driving, and the most important one of all, is that it adds much to the margin of safety.

Now if the four reasons given for moderate driving are not sufficient to affect car owners, nothing that could be said would have any effect upon them.

PRICES FOR PARTS.

Readers frequently complain at the high prices charged by manufacturers for automobile parts, and there seems to be a good reason for such complaints.

If any manufacturer of automobiles has a feeling of indifference towards those who have purchased his cars simply because the chance is remote that they will ever purchase another one, he is making a business mistake.

Car owners themselves have the power to sell more cars than either the manufacturers or their agents. It is true they may not exercise this power or influence to any great degree unless conditions and feelings are favorable. The car owner must have a feeling of obligation, not alone because he feels he received good value, for that is what he had reason to expect, but rather because of consideration received after having purchased his car, which of course is a favor rather than a right. Anything bestowed as a right is not specially conducive to gratitude, but that which is conferred from motives of good-will purely is bound to make a distinctly favorable impression.

It is a short-sighted policy for a car manufacturer to either charge exorbitant prices for parts or to in any way neglect the owners of his cars. More automobiles are sold by owners themselves recommending them to others than by any other means. And more sales are lost than by any other means by owners looking mysterious and wise but saying little when some one asks them how they like their car.

PRO AND CON OF WEIGHT.

In relation to the communication headed "Weight of Cars," elsewhere in this issue, it is true that with other things being equal, a light car is better than a heavy one, and possibly it may also be true that the weight of automobiles might be and should be reduced.

It should not be forgotten that manufacturers are constantly striving to reduce the weight of their cars, but that this is easier said than done. First, the factor of safety must be considered. On a smooth road and with an unvaried speed, quite likely a car might be constructed of less than half the ordinary weight, and yet it would bear the load without breaking down. But a test of this sort would be of absolutely no use whatever. When a car comes out of the factory, it must be able to stand a test, when loaded to its full capacity, of being driven over the worst of roads and upon the worst of grades. Not only must the margin of safety be sufficient to withstand this test, but it must be two or three times greater than such a test requires.

It is somewhat puzzling to the lay mind to know that in some cases heavy cars have been known to consume less fuel than lighter ones. Moreover, a reduction of weight of some parts of a car makes very little difference in the consumption of fuel, while if the weight of reciprocating parts, or the periphery of wheels—as for instance the tires or rims—be reduced, there is quite a pronounced reduction of the power needed to propel the car.

Of course the quality of the metals is important, and in this there is constant improvement being made. Not long ago malleable iron with a test of 25,000 pounds to the square inch was considered good iron, while to-day it will test from 30,000 to 33,000 pounds.

When our highways are all smooth and hard, automobiles may be built far lighter. It is the rough roads that cause undue strain, and none who has ridden in both light and heavy cars need be told how much easier the heavy cars ride on rough roads than light cars.

A GREAT SPEEDWAY.

The Sheepshead Bay Speedway in one of the suburbs of New York City is the most conspicuous monument thus far reared to the automobile and it is a decided credit to the enterprise and confidence of the men who projected it and brought it to its final completion.

It is by far the best and most expensive automobile race track in the world, and in itself is a sight worth going miles to see. No expense was spared in its construction, and its opening October 9, was an

Digitized by Google

epoch-making event, witnessing as it did the overthrow of foreign speed supremacy. It was seen by 60,000 spectators who will all want to go again. The second race, Nov. 2, brought out 35,000 enthusiasts. Particulars of these two events have already been published in the daily papers. Sufficient now to say that they were not marred by a single accident of any sort.

LESSONS FOR DRIVERS.

Carelessness and Ignorance Responsible for Most Accidents.

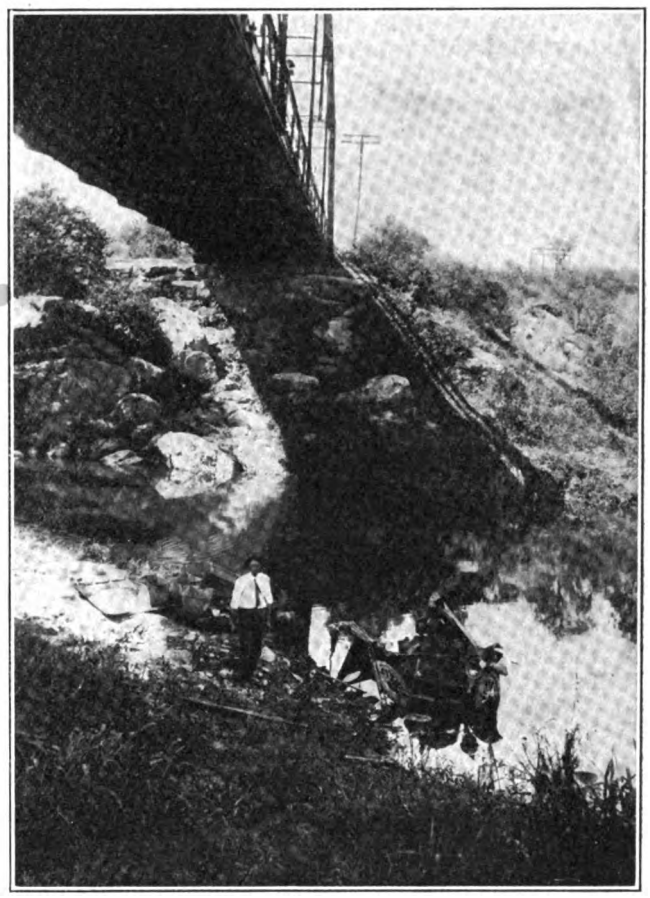
Lights Were Not Lit.—Two men were badly cut and otherwise injured near Oakland, Wis., when they drove up behind a buggy, which they did not see until too late, as their headlights were not lighted. The buggy was entirely demolished and the horse so injured that it had to be killed.

Racing with a Train.—A man lost control of his car near Sugar City, Utah, while racing with a train. The machine turned over and the man struck on his head, breaking the bones at the base of the brain and cutting his face. There is a little hope of his recovery.

Dust Obscures Car.—Two people were killed and three injured in a head-on collision near Hillsdale, Mich. It appears that the driver has passed a horse and buggy which was followed by two automobiles, and the dust of the first car obstructed the view of the following machine, with a result that a collision occurred. One woman was killed instantly and a young man died shortly after the accident.

Excessive Speed.—A young man with five companions were joy riding in New York City and while going at a rate of thirty miles an hour the car left the road and crashed into a steel telegraph pole, killing the young man and injuring his companions.

While Cranking His Car.—A man dropped dead at Washington, D. C., while in the act of cranking his car. It is presumed that the overtaxing of his strength brought on the attack.



Accident at Bad Crossing.—Four children and a driver were killed and two injured near Lancaster, Pa., when a collision occurred between an automobile loaded with school children and a train. Owing to a deep cut where the highway crosses the track neither the engineer nor the driver were able to see each other until too late.

Steering Gear Wheel Swept from the Driver.—An accident occurred at Cincinnati, O., when an automobile collided with a loaded lumber wagon, and a piece of projecting timber swept away the steering gear wheel of the car and caused the machine to dash into the rear end of the lumber wagon. The driver was struck with glass from the shattered windshield, severing the jugular vein. His recovery is doubtful. Another occupant of the car suffered two broken ribs.

Assumed That the Train Would Stop.—A family of seven, mother, five children and an aunt, were instantly killed and the father seriously injured at Fraser, Mich., when the car in which they were riding was struck by an express train. They were approaching the tracks of the railroad yard and the driver, if he saw the on-coming train, had the impression that it would stop, although it was not scheduled to do so. He took the chance of crossing the tracks with the above result.

Lumber Blocks Way.—A child was knocked down and instantly killed at Chicago, Ill., when she stepped from behind lumber and a tool box which blocked the street, into the path of an automobile. It is stated that notice was served on the contractor in charge of the constructing of the building but so far the latter had failed to remove the things.

Plunged Into a River.—In San Angelo, Texas, a young man and a car plunged through the side railing of a bridge down into a river thirty feet below. Only presence of mind saved the driver. Realizing that his machine was jumping off the structure, he caught a piece of broken railing as the car shot off into space. The speed of the auto dragged him from his hold and he dropped into the water directly in front of the machine a second after it struck. Rocks

Pretty Well Demolished.

in the river inflicted wounds in his head, but he was out of the water standing on the bank, dripping wet, when the first persons who heard the crash arrived. In a statement the young man said: "The steering gear had been loose for several days. There was too much play for one thing and when you turned the wheel it would not wind up. This was what happened when I hit the bridge coming to town. I grabbed the bridge and did not fall with the car."

At a Sharp Turn.—At Conneaut, O., two men were killed and three injured. The party were testing a new machine which one of them had just purchased. They were going at high speed and did not observe a sharp turn, and the car struck the curb and turned over.

Railway Crossing Accident.—Two women and a little boy were instantly killed and another woman's feet were crushed so the amputation of one was nec-

Digitized by Google

essary, in an accident at a railway crossing near Mosley, Mich. One of the women was driving and none of the occupants of the car seemed to note the approach of the train.

Did Not Heed Signal.—Two women and a man were killed at Gas City, Ind., by being struck by a locomotive and hurled many feet from the crossing. The chauffeur drove the car at high speed through the town and the watchman at the crossing signalled a warning but the driver of the car paid no heed. One woman's head was torn completely from her body, the other woman was crushed and the man's neck was broken. The chauffeur escaped with slight injuries.

Crossing Obscured.—A woman and her infant daughter were instantly killed at a railroad crossing near Arlington, Neb., and her husband and another woman severely injured, when they were struck by the engine of a freight train. As they approached the tracks the crossing was obscured by banks of earth, and the driver says that the warning bell was not ringing. It is stated that a number of serious accidents have occurred at this point.

Turned Corner Suddenly.—One little girl was instantly killed and another child knocked down and injured at Mt. Sterling, Ky., when a car suddenly appeared upon them around the corner without warning and before they could get out of the way they were struck.

Ran His Car Without Lights.—In running his car without lights, a man was killed and another man injured at Hartley, Ia. The car struck the iron railing of a bridge and pitched off the bridge twenty feet below into the bed of a creek.

Caused by Cramped Position of Driver.—Near Lawrenceburg, Ky., one man was instantly killed and three others injured when he lost control of the machine and was thrown through the windshield, striking the ground with such force that he was injured beyond recognition. As the car was a runabout and there were four occupants it is stated that the cramped position of the driver may have caused him to lose control of the car.

SOME LEGAL CASES.

Things Car Owners and Drivers Should Carefully Read and Remember.

Father's Liability for Son's Negligence.—The Texas Court of Civil Appeals holds that while an automobile is not a dangerous instrument, per se, when operated by a careful and competent driver, a powerful, heavy machine operated by an 85-pound boy, 11 years of age, along the streets of a populous town may become a menace to other persons in the street. A boy 11 years old, by permission of his father, purchased an automobile, which was kept in a garage. His father paid the bills and the boy had unlimited authority to call for the car at any time, day or night, and to use it, not only within the city limits, but in making excursions across the country to other towns; and his father and mother frequently accompanied him on such trips. The father arranged with the garage owner for the boy to have the car whenever he wanted it and paid all the bills and stated that whatever the boy did was right. While the boy was away at school for a few weeks, the car was cared for by the father and upon his return was delivered to him. While driving the car in a busy street in a city the boy ran down a woman who sued his father for her injuries. It was held that the boy in operating the car was the servant of the father, and therefore the latter was liable for the plaintiff's injuries.—Allen v. Bland, Texas Civil Appeals, 168 S. W. 35.

Automobile Collision.—In an action for injuries to the plaintiff's automobile in a collision with that of the defendant, which was being operated by the defendant's servant, it was held that the questions of the negligence or the wanton or willful negligence of the defendant's servant, and whether one having only one foot, as he did, could handle a car as efficiently as if he had two, and whether his operation of the car, and the defendant's putting him in charge was negligence, proximately producing the injury, were for the jury. A witness, merely because he was the secretary and sales agent of an automobile company, and had sold the defendant the car in question, was not thereby qualified as an expert on its mechanism or mechanical operation, so as to entitle him to give his opinions whether the car could be operated as safely by one crippled in one foot, as if he had the use of both. Blalack v. Blacksher, Alabama Court of Appeals, 66 So. 863.

Scope of Employment.—The owner of an automobile permitted his son to take the machine to give some friends a ride, on the condition that S. drive the car, as the son was not an expert driver. Owing to the negligence of S. the car was overturned, and one of the occupants, a guest of S., was seriously injured. She sued the owner of the car, on the theory that the relation of S. as to the defendant, on this occasion, was such as to render the defendant liable for the negligence of S. It was held that the owner was not liable, for, as to the plaintiff, S. was not the owner's servant.—Power v. Williamson, Alabama Supreme Court, 66 So. 585.

Theft Insurance.—An automobile was insured against loss or damage in excess of $25, occasioned by theft, robbery and pilferage. A boy took the car out of the garage where it was kept, for a joy ride, in the course of which he ran it into a fence, wrecked it and abandoned it. It was held that the owner of the car could not recover on the policy for damages caused by the wrongful taking of his machine by persons who intended to use it, but not to steal it, for an intention to steal is an essential to a conviction of robbery, theft or pilferage, and such words must be construed the same in an insurance policy as in ordinary cases.—Michigan Commercial Ins. Co. v. Mills, Indiana Appellate Court, 106 S. E. 725.

Owner's Liability.—A land company which was exploiting certain lands for sale at some distance from the city was in the habit of furnishing to prospective buyers an automobile and a driver to go to and from the property. It was held that the land company was legally responsible for injuries occurring through the negligence of the chauffeur of one of its automobiles while so engaged, if the chauffeur was found to be its servant.—Stovall v. Corey Highlands Land Co., Alabama Supreme Court, 66 So. 577.

Negligence in Moving Switch While Car is Being Cranked.—Action was brought by a chauffeur against his employer, the owner of an automobile, for injuries caused by a "back fire," which resulted in breaking his wrist. The plaintiff testified that just before he was injured the defendant directed him to crank the machine. He put the switch on

Digitized by Google

the batteries and set the lever in a retarding position on the operating wheel and went to the front of the wheel and started to crank it up, when the defendant touched some of the levers on the front of the machine, the plaintiff being in the act of cranking, when the back fire occurred. There was evidence that when the switch was on the magneto there was more danger of a back fire than when it was on the batteries. It appeared that the only way in which a back fire could have occurred was by the switch having been placed on the magneto. It was held that if, without the knowledge of the plaintiff, the defendant changed the position of the levers, while the plaintiff was cranking the machine, and knew that the probable consequences would be to cause a back fire, his act might be regarded as negligent. If he was ignorant of the consequences, and changed the position of the levers without knowing what the effect would be, he would be equally culpable. To interfere with the mechanism of the machine under such circumstances could be found to be an act lacking in reasonable care and prudence. It was therefore held that the jury were warranted in finding that the defendant was negligent in moving the switch while the plaintiff was cranking the car, and that the plaintiff was free from contributory negligence.—Norris v. Allen, Massachusetts Supreme Court, 105 N. E., 364.

Master Not Liable When Servant Not Liable.—Action was brought against the owners of an automobile and their servant for damages for personal injuries resulting from a collision caused, it was alleged, by the negligent operation of the machine. A verdict was rendered releasing the servant, but holding the master. This was held, on appeal, to be equivalent to finding no cause of action, and could not support a judgment against the master; the master being liable only in case the servant was liable, and the award of damages against the master being controlled by the determination that the facts did not exist which justified an award.—Pangburn v. Buick Motor Co., 211 N. Y. 228, 105 N. E., 423.

Regulation of Garages.—A regulation adopted by the municipal explosives commission of New York City, pursuant to Laws 1911, c. 899, making it unlawful for anyone to store any motor vehicle containing volatile inflammable oil except in a building for which a garage permit shall have been issued, and providing that no garage permit shall be issued for any building within 50 feet of the nearest wall of a building occupied as a school or place of public amusement or assembly, or occupied as a tenement house or hotel, is held to be a valid exercise of the police power, and not to deprive one of his property without due process of law or the equal protection of the law so far as it relates to new establishments of the kinds forbidden. The main objection made to the regulation was that it is made applicable to a building that had been used as a garage and for the storage of gasoline, lubricating and other oils, prior to the time the enactment took effect; and it was stated that in the city of New York there were 75 garages, some of them valuable structures, which would come within the provisions of the ordinance if it were declared valid. The court considered th- this did not furnish a sufficient argument to condemn the enactment, and held that it was valid as applied to buildings so used at the time of the adoption thereof.—In re McIntosh, New York Court of Appeals, 105 N. E. 414.

Proof Must Show Negligence of Driver.—In an action for negligently running over the plaintiff's dog by the defendant's automobile, only one witness testified to the occurrence. It appeared that the accident occurred during the daytime. The witness saw the dog in the road, and that it was run over by the car, which did not slow up, but was going at a moderate rate of speed. He afterwards saw the dog lying in the road. So far as the case showed, both automobile and dog were lawfully in the road. There was no evidence of careless driving. It was held that the mere fact that the automobile ran over the dog was not sufficient to support an action for negligence, much less for a willful injury, and that the plaintiff's case was not proved.—O'Hara v. Gould, New Jersey Supreme Court, 87 Atl. 117.

Collision with Street Car.—In an action against a street railroad for injuries from a collision of its car with the plaintiff's automobile, the trial court directed a non-suit. On appeal this was held to be error, because the evidence did not show conclusively, as a matter of law, that contributory negligence on the part of the plaintiff was the proximate cause of the collision. It was in evidence that the defendant's car was being operated at a speed of upwards of 20 miles an hour, far in excess of the limit of speed permitted by ordinance at the place of collision. It appeared that if the car had been operated at lawful speed the plaintiff's auto could have turned off the track to a place of safety. So far as appeared, nothing was done to stop the car after the auto came in plain sight of the motorman. Under the evidence as it stood, the jury would have been warranted in finding that the defendant was guilty of negligence in running its car at a reckless rate of speed in violation of the ordinance; that the plaintiff was not negligent, or that, if he was, the defendant could have stopped its car and have avoided the collision after it became evident that the plaintiff was going upon the car track. The defendant, it was held, should have been called upon to produce its evidence, and the case should have been submitted to the jury.—Berghman v. Rhode Island Co., Rhode Island Supreme Court, 87 Alt. 314.

Double or Treble Damages.—A complaint stated facts sufficient for a recovery under Connecticut Pub. Acts, 1909, c. 211, Section 11, prohibiting reckless driving of motor vehicles on a public highway, and also under Pub. Acts. 1905, c. 216, as amended by Pub. Acts 1909, c. 268, allowing double or treble damage for injuries caused by violation of the laws of the road. Both causes of action were submitted to the jury. It was held that the court could not, in the absence of a special verdict, indicating upon which cause of action recovery was allowed, give judgment for double the amount of damage awarded by the verdict.—Dunbar v. Jones, Connecticut Supreme Court, 87 Atl. 787.

Evidence of Driver's Negligence.—In an action for injury to a child of four years of age, by being struck by the defendant's automobile in a public street, it was held that a non-suit was amply justified. There was an entire absence of testimony that the defendant was traveling at an excessive speed, that he did not have his car under suitable control, or that he failed to exercise due care in any respect or at any time. There was no testimony to indicate that the plaintiff had left the sidewalk, where he was just before the accident, until the moment before he was hit, or that there was anything in the situation

Digitized by Google

which called for special prosecution on the defendant's part to avoid the accident which were not taken. On the contrary, the evidence indicated strongly that the plaintiff did not leave the walk, or come into a place of danger, until the defendant's car was so close to him that no reasonable efforts on its driver's part could have avoided running him down. The case was not one in which the plaintiff merely failed to present, as he was bound to do, evidence pointing to the defendant's negligence contributory to the injury; the evidence presented went far to disprove such negligence.—Hyde v. Hubinger, Connecticut Supreme Court, 87 Atl. 790.

Speed Regulation.—In proceedings for violating the Georgia statute regulating the speed of automobiles (Acts 1910, p. 92, Section 5), it was held that so much of the act regulating the use of automobiles as undertakes to make penal the operation of an automobile on the highways of the State. "at a rate of speed greater than is reasonable and proper, having regard to the traffic and use of such highway, or so as to endanger the life or limb of any person or the safety of any property," is too uncertain and indefinite in its terms to be capable of enforcement. The court of the accusation charging the accused with having operated an automobile "so as to endanger the life and limb of persons and the safety of property." was subject to special demurrer on the ground that it failed to show what person or what property was endangered by the running of the automobile.—Carter v. State, Georgia Court of Appeals, 78 S. E., 205.

State Regulation of Motor Vehicles.—Maryland Laws, 1910, chap. 207, provides that motor vehicles be registered, at a cost varying from $6 to $18, according to horsepower, that drivers obtain a license at a cost of $2, and that non-residents, in order to have limited use of the highways without cost, must have complied with a similar law in their respective States, and must have secured a local identifying tag or marker. The United States Supreme Court holds that these requirements are not so arbitrary or unreasonable as to constitute, when applied to vehicles moving in interstate commerce, a direct and material burden upon such commerce, and are therefore valid until displaced by federal legislation covering the subject.—Hendrick v. Maryland, 35 Sup. Court, 140.

Recovery for Injury to Rented Car.—In an action for injuries to the plaintiff's automobile, it appeared that the plaintiff was compelled to run his car across a depression on the side of the road in order to pass the defendant's team, which had been driven into the highway from a lane, and stopped diagonally across the way, leaving no space to the rear of the wagon through which the plaintiff's car could pass, and leaving the space in front so slight as to compel the plaintiff to run into the depression in passing. It was held that the defendant's negligence and the plaintiff's contributory negligence, if any, were questions for the jury, which found in favor of the plaintiff. The plaintiff was operating the car under an agreement with the owner for a division of profits and that the plaintiff would return the car in as good condition as when he took it, necessary wear excepted. It was held under this agreement the plaintiff could recover for the damages to the car, although not its owner.—Manion v. Loomis Sanatorium, 147 N. Y. Supp. 761.

CARBURETOR RUDIMENTS.

Principles of the Vaporizer That Makes Fuel for Automobiles.

A car driver should know something of the theory and construction of his carburetor. The beginner finds many difficulties in his way, as he probably reads the maker's catalogue and description of what is really a somewhat intricate device, without first understanding the theory of its operation. Makers' descriptions seem to be intended for experienced people. It is the object, therefore, by describing an elementary form of carburetor to enable those who wish to pursue the subject further to understand the more complicated constructions now in use, and the general principles underlying the action of all carburetors.

The function of the carburetor is to convert the liquid gasoline into a gas, to mix that gas with air, and to deliver the required quantity of mixture to the engine. A liquid will not burn, and therefore before the gasoline can be used in the engine it must be changed into gas. In the earliest carburetors the air was passed over the surface of the gasoline, some of which was thus evaporated and taken up by the

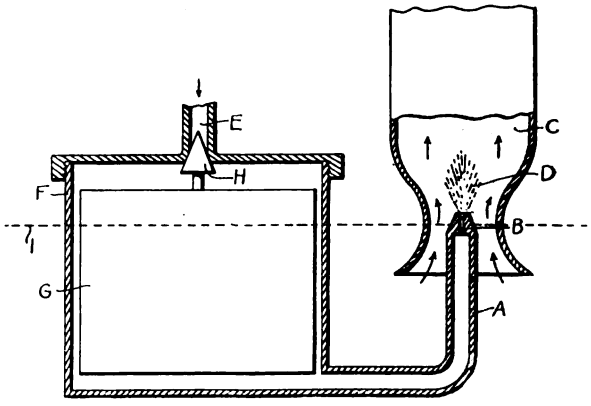


Fig. 1.

air. This principle was not found generally satisfactory.

An alternative to the simple surface carburetor is to have a number of wicks dipping in gasoline and to draw the air through these so that in passing it takes up some of the gasoline from the wicks by evaporation. It is necessary to heat the air before it passes through the wicks, and, after it has been carbureted by the addition of the gasoline vapor, the correct mixture must be obtained by the addition of more air. The mixture then passes through a throttle valve to the engine. As this system is so simple it is unnecessary to illustrate it.

In the spray carburetor the essential feature is the spraying nozzle or jet. Most people have handled a scent spray, in which there is a vertical tube dipping into the scent bottle and provided with a small hole at the upper end. Near this upper end is an air tube through which air is blown forcibly by means of a bellows device. This air passes over the top of the vertical tube, and by its movement causes some liquid to flow up the tube and to pass out through the small hole at the top. By the speed of the air passing, and on account of the small size of the hole, the scent issues in a thin stream and is broken up into thousands of tiny globules which rapidly disappear, showing that they are turned from the liquid globular form into vapor. This scent spray idea

Digitized by Google

although hardly recognizable is the principle upon which all spray carburetors operate.

Construction of the Spray Type.

The simplest form of spray carburetor is shown in Fig. 1. At the right-hand side is shown a vertical jet tube, A, containing gasoline and terminating at its upper end in a hole of small bore, B. Around this is a pipe, C, which is constructed in the neighborhood of the jet, and which leads to the inlet valve of the engine. At each suction stroke of the engine air is sucked through the pipe, as shown by the arrows, and as the pipe is restricted the air passes the top of the jet at high speed; for this reason, and also because of the suction effect generated, the gasoline is caused to flow out and is broken up into a fine spray (as in the scent squirt), D. The smaller the hole in the jet the less gasoline will issue in relation to the air passing, and conversely the less the pipe is restricted the more air there will be, so that by adjusting the relative sizes of the jet outlet and the restriction in the neighborhood of the jet, the correct mixture is roughly obtained. More delicate adjustment than this is required, however, as will be explained later. The most powerful explosion is obtained when the gasoline vapor is mixed with a certain definite quantity of air. If there be too little or too much gasoline vapor, the power to the engine will fall off, and in the latter case the gasoline consumption will also be heavy. It is, therefore, extremely important that the right proportions of gasoline to air should be maintained under all conditions, and it is on account of the delicate adjustment required to accomplish this that carburetors are somewhat complicated.

The Float Chamber.

If the level of the gasoline in the reservoir from which it is drawn were above the top of the jet orifice, gasoline would flow from the latter when the

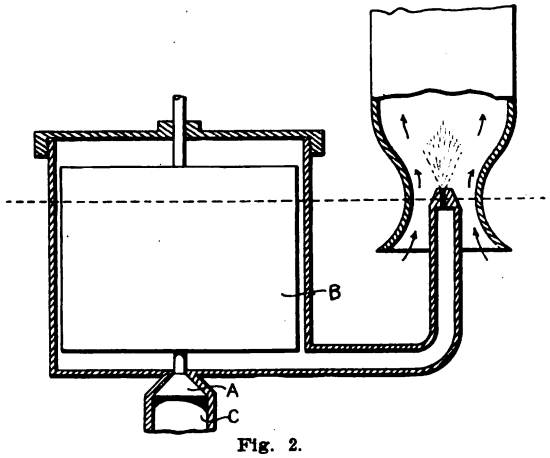

Fig. 2.

engine was stopped. Therefore some device must be employed to keep the gasoline at the required height in the jet. To do this a float feed mechanism is used, and this is contained in a float chamber alongside the jet nozzle. In the crude form shown in Fig. 1, the gasoline is admitted to the top, E, of the float chamber, F, containing a cork or hollow metal float, G, to the top of which is attached a conical plug or "needle," as it is termed, H. As the gasoline flows into the chamber the float rises until a certain height of liquid is obtained, when the needle (which, of course rises with the float) closes the gasoline inlet. When the gasoline level falls in consequence of some passing out of the jet nozzle the float falls and more gasoline enters, so that the gasoline level is automatically kept at the correct height, which is shown by the dotted line, I.

As stated, the float feed mechanism described is of a crude type which is rarely used. Another form is shown in Fig. 2. Here the needle, A, which again takes the form of a plug, is fitted to a rod attached to the float, B, and the gasoline enters from below at C. When the required gasoline level has been reached the float has risen to such an extent that the needle blocks the entry to the float chamber.

The most usual float feed mechanism is shown in

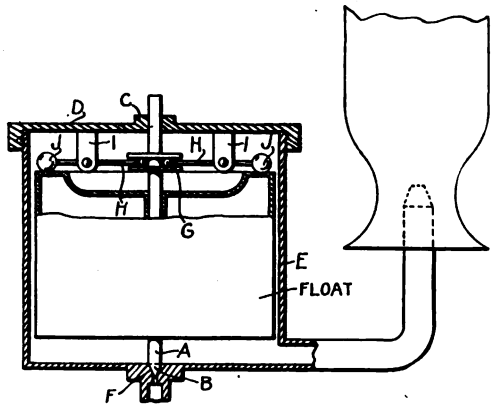

Fig. 3.

Fig. 3, where the mechanism is shown as in use. The float in this case is formed with a passage through the center, and is generally made hollow and of metal. Through the central passage passes a rod, A, the lower end of which is pointed somewhat resembling a needle, B, as in fact it is termed. The upper end of the needle passes through a guide, C, in the lid, D, of the float chamber, E, and the lower pointed end engages a coned seat, F, past which the gasoline must flow in order to enter the carburetor. Attached to the needle is a reel, G, and between collars on this reel lie the ends of a pair of levers, H. These levers rock on pivots, I, attached to the lid, D, of the float chamber, and at the ends opposite to the reel the levers are provided with weights, J, which tend to lift the needle off its seating. These weighted ends rest upon the edge of the float. Thus, when the gasoline is turned on the float rises, and the weighted ends of the levers are gradually raised and their inner ends lowered, pushing down the needle valve until it closes the gasoline inlet to the float chamber. As the gasoline is used the level falls and the float drops, so that the weighted ends of the levers lift the needle valve and more gasoline is admitted.

In nearly all cases the upper end of the needle projects above the lid of the float chamber, as shown in Fig. 3, but in some instances this upper end is closed in by a cap, and if this cap be unscrewed the upper end of the needle can be seen. When the engine is running this needle should, of course, be down. If the gasoline tap be turned off and the engine run, the needle will gradually rise, due to the gasoline in the carburetor being slowly used up, causing the float to fall. It is as well to bear this in mind, as the position of the needle can be taken as an indication, which is often useful if the engine stops, as to whether the float chamber is full or not. On looking at the needle one can tell whether the stoppage is due to running short of gasoline or to some restriction in the jet.

Digitized by Google

Choke Tubes.

Reverting to the crude carburetor shown in Fig. 1, it will be noticed in that diagram that the lower part of the spraying chamber is restricted in the neighborhood of the jet nozzle. If a sectional drawing of a carburetor can be examined it will be seen that the passage round the jet is narrower than the space above it, but in some cases, instead of the wall of the spraying chamber being narrowed, a separate tapered tube, termed a choke tube, is used. By using a larger or smaller choke tube the carburetor can be adjusted to suit different engines. In some carburetors a choke tube of this type is not used.

Assuming that the crude carburetor shown in Fig. 1 is fitted to an engine which is running satisfactorily at 500 revolutions per minute, if the engine is to run faster, the air in consequence will travel faster past the jet nozzle and more gasoline will flow out of the jet. For a number of reasons, which it is unnecessary to discuss here, it happens that more will flow out than is required. That is to say, the faster the engine runs the richer becomes the mixture. Correspondingly if the engine run slower the

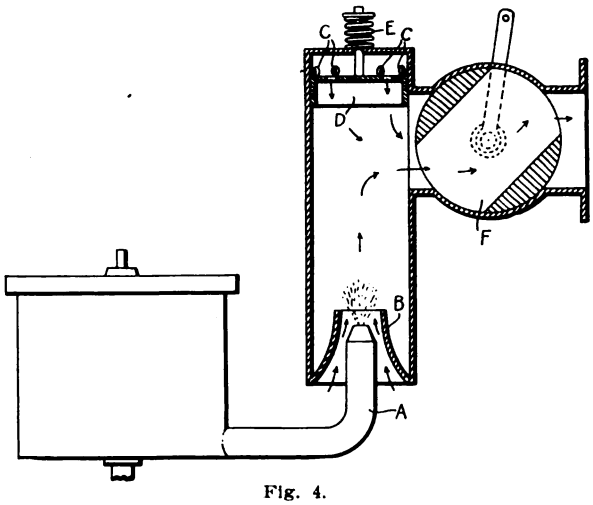

Fig. 4.

delivery of gasoline from the jet falls off and the mixture becomes weak. As it is necessary to keep the same proportion of gasoline to air at all speeds, it is clear that a simple form of carburetor like this will not be satisfactory under all conditions, and that to make it satisfactory one must supply more air or reduce the gasoline supply in order to correct the mixture as the engine runs faster.

Automatic Adjustments.

A simple form of automatic carburetor which does the former is shown in Fig. 4. Here there is a jet, A, surrounded by a choke tube, B, the size of which and the jet outlet are so arranged that the engine receives a proper mixture at low speed. When the engine speeds up this mixture becomes too rich, and must be diluted with pure air, for which purpose an extra air inlet is used. At the top of the carburetor is a number of holes, C, for the admission of air. These holes are normally shut off by a piston, D, which, at low speeds, is supported in position by a spring, E, so that no air then enters by these holes, but as the engine runs faster the suction becomes powerful enough to draw the piston downwards to a varying extent, uncovering the air ports and admitting extra air to dilute the rich mixture. As the engine slows down the piston automatically rises and shuts off these extra air inlets, so that the mixture is then prevented from becoming too weak. On the right hand side is a throttle valve, F, which acts merely as a tap whereby the quantity of gas passing from the carburetor to the engine may be varied.

Heating the Air.

The evaporation of a liquid causes a fall in temperature, as one soon appreciates if one stands in a wind with wet clothes on. To evaporate a liquid heat must be taken up from the surrounding objects, and consequently a carburetor becomes a refrigerating plant on a small scale, and even in summer the outside of some carburetors under certain conditions becomes coated with frost, due to the low temperature inside causing the moisture in the air around the carburetor to freeze. In cold weather the air passing through the carburetor may deposit frozen moisture to such an extent that the spraying chamber may become choked with ice and the carburetor "frozen up." (There is a widespread misunderstanding about this, it being often supposed that it is the gasoline which freezes, but this is not the case.) To prevent this freezing, and because the carburetor will not work well at low temperatures, it is essential to heat either the incoming air or the carburetor itself. For this reason the air is drawn from the neighborhood of the exhaust pipe, or some other point from which it can obtain heat, or the carburetor is fitted with a hot water or hot air jacket through which hot water or exhaust gas is passed.

It must be pointed out that there is a big difference between the simple construction described and the actual types of carburetors most widely used, and the beginner will probably find much difficulty in finding any resemblance between his carburetor and that dealt with, beyond the float mechanism.

RUNNING FORD CARS.

An Englishman's Advice as to Their Care and Management.

From "Vagrant" in the London Autocar.—In venturing to make suggestions for the benefit of fellow Ford owners, I feel that I am in rather a curious position, for there must be many motorists in this country who have covered on the car in question far greater mileages than stand to my credit, though my own experience extends to 22,000 miles covered in just two years and a half.

From the point of view of mileage alone some other Ford owners undoubtedly have the advantage of me, but I rather doubt whether any of them has had more opportunities than I have enjoyed for considering the Ford not alone upon its own merits but in comparison with other cars.

I have owned motorcycles, a steam car and various different makes of well-known gasoline cars during the past fifteen years, and, as I have always been my own mechanic I have obtained a fair insight into the capabilities and limitations of each one of them. I knew precisely what they would do and what was beyond their powers, and I have the same knowledge in connection with the Ford I own to-day.

This comprehensive experience, therefore, may help me to be of some material assistance not only to motorists who have owned no other car than a Ford, but also to those who, owning or having owned another make, may contemplate the purchase of a

Digitized by Google

Ford, not realizing in the least in what important respects that car differs from others.

Fuel Consumption.

To run the car economically is, I suppose, one of the principal aims of most motorists, be the vehicle in question a Ford or anything else; and, whatever the make may be, there are, of course, certain principles to be taken into account and ideals to be striven for which are common to all cases. For example, we all wish to cut down gasoline consumption, but with the majority of carburetors this is not altogether an easy matter. One can change jets, choke tubes, the gasoline level, and other details of the kind, but, as a rule, the alteration takes time, and, although the result in a given set of circumstances may constitute an improvement, it by no means follows that the revised setting will give satisfaction throughout a day's running.

Now a Ford is fitted with a Holley carburetor, in connection with which there is only one adjustment, namely, the size of the spraying jet. Obviously, for economical running, the amount of gasoline passing the jet should be as little as will give the amount of power required at the moment; but, if we cut down the gasoline to suit the needs of the engine when the car is running easily—say down a gentle slope or before a following wind—we shall not have full power, if we require it, for hill-climbing. With the Holley carburetor, with very little trouble one can obtain the desired result whether the work of the engine happens at the moment to be light or heavy.

The jet aperture has passing down into it a needle, the spindle of which is threaded so that when the button on the top of the spindle is turned clockwise the needle is forced down into the jet aperture until, eventually, it closes it altogether, and when turned counter-clockwise the needle is raised, enlarging the jet aperture to a less or greater amount as desired. By means of a long rod, terminating at its upper end in a brass-headed button, the control of the carburetor needle is brought up to the driver's side of the dashboard, and upon the correct manipulation of this button a great deal depends.

If I remember rightly the Ford Company used, at one time, to set the needle so as to give the maximum engine power, and then were in the habit of advising Ford owners to leave that setting alone. In my opinion this advice was unfortunate, for the engine is quite a heavy drinker when pulling hard, whereas it may be described as practically a teetotaller when the work to which it is put is light.

The cardinal rule for saving gasoline on the Ford car is to run with the button on the dash screwed clockwise as far as possible without losing power. The only objection to running always on the weakest mixture that will serve is that the requirements alter in the course of a day's run almost from minute to minute, and to achieve the very best results possible for each change of condition requires a corresponding movement of the brass-headed button, which on the standard Ford is placed in an awkward position on the dash. At least two devices have been introduced recently for simplifying the manipulation of the button, the object of both of them being to bring the control right up to the steering column just below the steering wheel. I have one of them fitted to my own Ford, and am more than pleased with it. By careful manipulation of the button I have obtained, with a four-five-seated car, 42 miles to the gallon—a mileage secured, I have no doubt, by some other Ford owners, but very greatly in excess of the average recorded.

To Obtain an Easy Start.

While on the subject of carburetor adjustment, it may be well if I say a word or two about the best method of obtaining an easy start with the Ford engine. Now the Ford, for some reason or other, has the reputation of being a bad starter, especially when cold, but my own experience is that it is one of the easiest engines to start, so long as one knows how to set about the matter.

The problem of easy starting with the Ford is really affected not only by carburetion, but by the setting of the vibrators on the four ignition induction coils. See, first of all, that each vibrator blade is adjusted as lightly as possible. When the engine is running, slack back the vibrator adjusting screw of each coil in turn until that particular cylinder ceases to fire; then tighten the screw until the cylinder cuts in again, and, finally, tighten again about one-eighth of a turn. When this setting has been obtained the conditions, so far as ignition is concerned, are satisfactory for easy starting.

Now as to carburetion. Note the position of the mark—generally a V-shaped nick—on the jet adjusting button on the dash when the engine appears to be developing its maximum power on the level. Let us say that the mark on the button in these conditions points due north, or towards the front of the car. For starting from cold, first turn the button counter-clockwise half a revolution until the mark points due south. Open the throttle to about the notch which gives twenty miles an hour speed on the flat. Retard the spark either completely or to within two or three notches of the lever's backward travel. Do not switch on, but go to the starting handle, and, by means of the wire controlling the butterfly throttle in the main air intake pipe, shut off the main air supply. With the wire drawn out turn the engine four half revolutions; in other words, pull up on the starting handle four times. Then let go the wire in your left hand, switch on the current, and give one smart pull up on the starting handle.

The engine should fire immediately. If it does not, give two or three more upward pulls on the starting handle without touching the air throttle wire. If everything be in order, the engine will certainly start at either the first or the second pull after the ignition is switched on.

When the engine has begun to fire, close the throttle a few notches, and gradually turn the carburetor regulating button clockwise until the mark is due north once more. Should the engine be unintentionally stopped when it is thoroughly warm, do not, when trying to restart, pull out the air throttle wire, for if difficulty be experienced in obtaining an explosion it will be due, in all probability, to an over-rich mixture and not to a mixture that is too weak. Also, when restarting the hot engine do not turn the carburetor regulating button counter-clockwise: it may even be necessary to rotate the button clockwise for about five-eighths of a revolution until the jet is completely closed, and then to turn the engine over half a dozen times by means of the starting handle to get rid of the over-rich mixture. After this has been done the due north position of the regulating button should be adopted again.

Incidentally, when starting the Ford from cold be

Digitized by Google

sure that the side brake is hard on. If possible, put a chock of some kind under one of the wheels, to discourage any tendency for the car to run forward when the engine starts.

Economical Running.

To revert to the subject of economical running generally, the annual bills can be reduced materially if attention be paid to husbanding tires, and, incidentally, all the mechanical units of the chassis. In the case of the Ford the chief point to bear in mind is that excessive speed, especially when long continued, is almost certain to lead to serious trouble. We all know that high speed on any car is bad for tires, and, naturally, this is so when the Ford is in question; therefore I will not labor that point, but will confine myself to a few words on its effect upon the chassis.

It must be remembered from the start, and all the time, that the Ford is not a racing car; that its designer does not advocate high speed being maintained on it; and that optimistic agents who talk glibly of an average speed of thirty miles an hour over a long day's run with the Ford are, in reality, doing the car a thoroughly bad turn by endowing it with capabilities it does not possess. If one drive a Ford at an average speed of twenty miles an hour it will last for years, but averaging thirty would certainly ruin it in less than three months.

I need hardly say that it is impolitic to avail oneself to the full of the Ford's remarkable power of acceleration. A big engine and a very light load naturally make for exceptional acceleration, but if the engine be habitually asked to do its utmost in this respect the tire wear will be considerable and the transmission will become prematurely aged.

Changing Gear.

Many people are apt to think that with epicyclic gearing a smooth change of speed must necessarily be obtained. This is by no means the case with the Ford gears. To secure a smooth change with this car it is necessary, after speeding up to, say, seven miles an hour on the low gear, to close the throttle as the foot comes back into the top speed position, the ideal being reached when the speed of the engine immediately before and immediately after the top gear clutch engages is unchanged. If the throttle be closed too much, there will be a jerk as the road wheels and transmission begin to drive the engine; if it be not closed enough there will also be a jerk, this time because the engine speed will be suddenly checked when the clutch plates grip. A little practice, coupled with common sense, should ensure a smooth change.

Working Together.

Upon his recent return from a trip through the West, Alfred Reeves, general manager of the National Automobile Chamber of Commerce, announced the formation of the Automobile Service Managers Association of Michigan, with headquarters in Detroit, and to have as members the service department men of the motor car concerns in Michigan, Northern Ohio and Western Ontario.

The purposes of the association are to promote personal acquaintance among the representatives of the service and repair parts departments of motor vehicle manufacturing companies; to consider the best methods of conducting the work of service and repairs; to promote the adoption of the most liberal policy of helpfulness to purchasers of motor vehicles, and to generally improve and facilitate cooperation among manufacturers, dealers and owners, with a view toward supplying the maximum of service to the mutual advantage of all.

Meetings will be held every month, at which papers on the problems of service will be read and discussed, with lectures and moving pictures of men and machines in factories and their operations.

The Indianapolis service managers have already been organized, and associations will be formed in Chicago and probably in Cleveland.

ANTI-FREEZING.

Now Guard Against Damage to the Radiator of Your Car.

BY C. P. SHATTUCK, M. E.

Automobilists, especially the motorist making his initial investment, will find upon consulting the instruction book accompanying the car a paragraph cautioning him to guard against freezing of the water of the cooling system. Generally instructions are given for the preparation and use of solutions to lower the freezing point of the water, but as the car is usually purchased in warm weather, the instruction book is likely to be mislaid or the suggestions for the care of the cooling system in cold weather forgotten.

It is reasonable to assume that the temperature will drop well below the freezing point this month and the motorist who would avoid the heavy expense of replacing cracked cylinders, water connections and pumps with new, and who does not desire to incur the cost of radiator repairing, will do either one of two things, namely, draw off the water from the circulating system when the car is not in use, or employ an anti-freezing solution.

Opinion varies as to the best solution to employ, some car makers recommending alcohol while others favor a solution with calcium chloride as the base. Others favor glycerine and some approve of alcohol and glycerine. Some manufacturers disapprove of the use of anti-freezing solutions because of their action upon the components of the cooling system. It is held that alkaline solutions are productive of an electrical action wherever two dissimilar metals are utilized, such as the brass tubing of a radiator and the solder used at the joints; the iron water jackets and the brass or aluminum plates, etc. While electrolytic action is to be expected when two metals of different potentials are used together in any alkaline solution, the injury resulting from such action will be minor as the solution is employed but a few months.

In selecting an anti-freezing solution the motorist must be governed by conditions of locality and the car. Where extreme changes occur; that is, in sections where the weather is mild for a few days then follows a sudden change to temperatures well below the freezing point, it is advisable to employ a solution that does not boil readily in mild weather. This is particularly true if the car be operated in heavy traffic or the motor is run idle for any great length of time. Under such conditions the freezing point will rise because of the evaporation that takes place. Another factor to be considered is the motor and its cooling system. Some motors will not heat

Digitized by Google

in warm weather under the most severe conditions of service while the water in others will boil readily. This is true of cars that have seen considerable service.

Of the solutions that can be prepared by the motorist no one combines all of the desirable features, so in selecting the solution it should be borne in mind that it should have no corrosive action, nor should its use prove deleterious on the components of the cooling system. It must be easily dissolved or combined with water, must be reasonably cheap and not subject to rapid waste by evaporation. It should not deposit sediment or foreign elements, its boiling point should be as high, if not higher than that of water, and it should not congeal at temperatures ordinarily met with where it is used.

The calcium chloride solution is favored by many car manufacturers and is easily prepared. One should be careful to obtain the chemically pure material, not the commercial form. The relative value of the solution is given in an accompanying table.

Alcohol, denatured, is perhaps, more extensively employed as it is easily obtained, combines readily with water and is not as expensive as the glycerine solution. One of the disadvantages of the alcohol solution is that it boils more readily than water and there is a loss by evaporation, particularly if the solution be prepared for freezing points in the neighborhood of zero Fahrenheit, and is used where the thermometer frequently registers above the freezing point, 32 degrees. The odor given off by the solution when heated is disagreeable to some. If the alcohol solution be employed care must be exercised. It should be tested from time to time to ascertain the loss of alcohol, or in other words the solution must be maintained at the desired point. There is an instrument or thermometer marketed called the pyrometer which will register accurately the freezing point of the solution. Another disadvantage of the alcohol solution is that it is not adaptable to radiators having a tendency to leak.

The glycerine, or alcohol and glycerine solution is favored by many because it does not heat as readily as alcohol and the glycerine preparation will not boil as easily as water. It is more expensive than calcium chloride or alcohol and has a tendency to attack the rubber hose of the circulating system. Glycerine creeps, its analogy being similar to that of the creeping of the electrolyte of a storage battery. The glycerine solution, even when combined with alcohol and water, is more practical than the calcium chloride or alcohol in motors heating easily and in radiators that are not perfectly tight.

The accompanying table show the the various combinations and their freezing points Fahrenheit, and the capacity of the cooling system can be ascertained from the maker or by drawing off the water and measuring it. Before introducing any solution, any existing leaks should be remedied else the cost of maintaining the solution will be expensive. The radiator should be thoroughly cleaned by using a soda solution or a marketed preparation. If the circulation system is badly affected with what is termed "fur" or scale, caused by the use of hard water, it can be cleaned by the use of washing soda, followed by hydrochloric acid. Employ a 25 per cent solution of the commercial grade, which should do the work in about 15 or 20 minutes. The system should be washed out thoroughly after using both solutions.

Calcium Chloride.

2 pounds	1 gallon water	Freezing point	18° F.
3 pounds	1 gallon water	Freezing point	1.5° F.
4 pounds	1 gallon water	Freezing point	—17° F.
5 pounds	1 gallon water	Freezing point	—39° F.

Alcohol.

Per cent.	Per cent.		
Alcohol 5	Water 95	Freezing point	25° F.
Alcohol 15	Water 85	Freezing point	11° F.
Alcohol 20	Water 80	Freezing point	5° F.
Alcohol 30	Water 70	Freezing point	—5° F.
Alcohol 35	Water 65	Freezing point	—16° F.

Glycerine.

Per cent.	Per cent.		
Glycerine 10	Water 90	Freezing point	28° F
Glycerine 30	Water 70	Freezing point	15° F.
Glycerine 40	Water 60	Freezing point	5°
Glycerine 48	Water 52	Freezing point	0° F.
Glycerine 54	Water 46	Freezing point	—5° F.
Glycerine 58	Water 42	Freezing point	—10° F.

Alcohol-Glycerine.

(Equal proportions.)

Per cent.	Per cent.		
Alcohol-Glycerine 15	Water 85	Freezing point	20° F.
Alcohol-Glycerine 20	Water 80	Freezing point	15° F.
Alcohol-Glycerine 25	Water 75	Freezing point	8° F.
Alcohol-Glycerine 27	Water 73	Freezing point	5° F.
Alcohol-Glycerine 29	Water 71	Freezing point	0° F.
Alcohol-Glycerine 30	Water 70	Freezing point	—5° F.
Alcohol-Glycerine 32	Water 68	Freezing point	—15° F.
Alcohol-Glycerine 40	Water 60	Freezing point	—23° F.

In addition to the anti-freezing solutions described there are marketed preparations which have a low freezing point and which do not boil below 210 degrees Fahrenheit, the boiling point of water. In selecting any solution for service in a radiator that has been repaired by a chemical preparation, it is well to ascertain from the maker of the last named the effect the anti-freezing mixture will have upon the preparation.

Those who do not care to employ an anti-freezing solution or whose radiators leak slightly will insure against the bursting effect of congealed water by draining the circulation system. This is practical with the majority of cars but not with some older types, the petcocks of which are not all located at the lowest point in the system, preventing a complete drainage. A careful inspection will determine this point and will prevent damage.

If through carelessness the car has been exposed to freezing temperatures it is advisable to ascertain whether or not the water is frozen before attempting to start the car, particularly if the machine be equipped with a motor starter. It is much better to remove the radiator cap and examine the water or open a petcock to see if the water flows than to shear off the driving mechanism of the pump. By assuming that the car will freeze if not properly cared for will insure the motorist against large repair bills occasioned by Jack Frost.

A Sweeping Claim.

From a Motorist, North Carolina.—I see in the September issue a statement about the Ford's pulling qualities. Mr. Boucher is the man that is not "motor wise," for when a Ford is running good and pulling good, it will pull any hill his six-cylinder car will pull, whether in Arizona or Virginia, or anywhere else for that matter, for I have tried about as many as he ever has, I suppose.

The Atwater-Kent System.

From John A. Brown, Rhode Island.—Please tell No. 1670, in your last issue, to avoid changing his Ford ignition. But if he must, he will find that the Atwater-Kent system meets every requirement.

Digitized by Google

SPIRAL BEVEL GEARS.

They Run Quiet, Have Good Wearing Qualities and Are Efficient.

A. L. Stewart before the New York Society of Automobile Engineers.—Several different names have been applied to the type of gear under discussion. It has been variously called "spiral bevel," "worm bevel," "helical bevel," "screw bevel," "spiral type bevel," and so on. Probably the last term ("spiral type bevel") more nearly describes the gear than any of the others. So far as I know, all gears of this type which are being made are approximations to a true spiral curve. There is no particular virtue in a spiral curve, but it will be seen that the term "spiral bevel" is not strictly correct. The term "worm bevel" suggests a sliding contact and does not seem to apply to the rolling action of bevel gears, although they have curved teeth which, if developed in a plane, would be a straight line. The shape of tooth which is actually being produced, however, is a curve when developed in a plane, and is close to a true spiral, so that "spiral type" aptly applies. It is interesting to note that spiral type gears are more appropriately named than so-called gears of spur type. The tooth of a spur spiral is a true helix and does not even approximate a spiral curve.

The essential feature of a spiral bevel gear is that the tooth is curved instead of straight; the curve, if continued, would intersect the cone center of the gear. This at once distinguishes the spiral from the skew bevel gear, the tooth elements being straight but not intersecting the cone center in the case of the latter. The tooth elements of a skew bevel are all tangent to a circle about the cone center, the diameter of this circle determining the amount of skew of the teeth.

Method of Cutting.

The method of cutting with which I am most familiar is that of the Gleason spiral type bevel gear generator. In this machine a face mill cutter is used. The impression has existed in some quarters that the cutter blades are formed to the shape of a tooth space, but this is not the case, each blade being ground to rack form. The cutter and the work are rolled together with a generating motion producing true octoid teeth or, as we commonly call them, involute teeth. The diameter of the cutter is 12 inches, so that the curve of the tooth is a circular arc on a 6-inch radius. In a large number of cases that have been laid out covering the full range of automobile gears of different pitches, diameters, face lengths and spiral angles, it has been found that this curve closely approximates in every case a true spiral. This is not considered to be either an advantage or a disadvantage; the point is mentioned as showing how the 12-inch diameter was chosen.

In cutting, one side of a tooth is finished at a time. On account of the large number of blades in action—ten cutting inside and ten outside—the machine is a rapid producer. The same cutter is used for both sides of the tooth and for both pinion and gear. One cutter will finish all pitches between 2½ and 7½ diametral as far as the tooth thickness is concerned, but different cutters are required for a change in angle of spiral. In practice it is found that four finishing cutters cover the usual range of automobile gears and pinions. The cutter can be set above or below the cone center of the gear to give right- or left-hand spiral. It can also be adjusted horizontally, the horizontal and vertical adjustments together allowing for cutting gears of different cone distances and angles of spiral.

Advantages.

In speaking of the advantage of spiral type bevel gears we immediately think of quietness, and this, of course, is the point which has led to their great popularity among automobile and axle designers, manufacturers and users. When all that could possibly be called over-enthusiastic praise has been lain aside, the fact remains that spiral type bevel gears are extremely quiet. It is easy to make them so in manufacture and to maintain them so in use and to a very great extent they have lessened the troubles of the axle man. The overlapping of the teeth, which is largely the cause of this quietness, is familiar in helical gears of spur type, and has long been used where high speed and quietness are required. In comparing spiral type bevel and helical spur gears, however, it must be remembered that spurs with axes not parallel have a sliding action and enter the worm and worm-wheel class. This is not true of spiral type bevels, and the comparison should be made only with helical spurs on parallel shafts, where the action is as purely a rolling action as in the case of straight-tooth spur gears. Line contact, not point contact is provided, the line slanting across the tooth face from the point at one end of the face, across the pitch line at the center and down to the flank at the other end.

Another marked advantage of the spiral type bevels is the range of endwise adjustment of the pinion that is possible without reducing materially the amount of bearing, or introducing noise. This is perhaps the most striking feature of these gears when tried out on the testing machine. An average of a large number of different combinations and pitches that have been tried showed that they would pass inspection with the pinion anywhere within a total range of .015 in., i.e., .007-in. or .008-in. each way from the flush position. A similar test of straight-tooth gears showed an average adjustment of only .008-in., or .004-in. each way. Beyond this adjustment the straight-tooth gears immediately became decidedly noisy, while the spiral type remained quiet through a much wider range than the .015-in., but showed a gradual change in the amount and position of the bearing.

This range of adjustment should be considered in connection with another feature, which I believe is peculiar to the Gleason method of cutting. Because of the fact that the same cutter is used for both sides of the tooth, the concave side, cut with the outside of the cutter, is on a slightly greater radius than the convex side, which is cut with the inside of the cutter. This produces a bearing heavy at the center of the face, and fading away slightly toward either end. If the gear and pinion housings were absolutely rigid, this peculiarity of the bearing would have no special advantage. But such a condition could not exist without the use of housing far heavier than would be tolerated, and the fact is that almost any axle will show displacement of the driving gear and pinion with relation to each other where the load is heavy. This weave of parts tends to throw the bearings toward one end or the other of the tooth. A bearing originally heavy in the center, allows for such displacement, without throwing the

Digitized by Google

load to a point bearing at either end of the tooth. This action is demonstrated in practice by examining gears that have been run with a light load, say on a testing machine, and then put in service in the axle. The first test will show the tooth surface polished at the center of the face, and at the second examination the tooth surface will be polished over the entire length. It has frequently been said that straight-tooth gears would be quiet enough if they could be set in absolutely perfect alignment and maintained so under all conditions of service, and it is known that straight-tooth bevels that run almost without a sound on a testing machine are frequently rejected in the axle test. In view of this any allowable adjustment or displacement of spiral type bevels is of very great importance.

The possibility of using higher ratios in spiral type bevel gears is an advantage which has been quickly recognized. In straight-tooth gears ratios of 4½ to 1 have been about at the dividing line between quiet and noisy gears in automobile drives, and for the high ratios there has been little chance of using a bevel gear drive. We have heard of occasional instances of straight-tooth gears being used for higher reductions, but usually in such cases considerable difficulty has been encountered. We know at present of several 5 and 6 to 1 ratios of spiral type bevel gears giving satisfactory service. In one 6 to 1 ratio the pinion has 11 teeth. In another case a 10-tooth pinion running with a 49-tooth gear has proved an entirely successful drive, while tests of a 9-tooth pinion in a 7.3 to 1 combination have also been quite satisfactory. I am of the opinion that the limit has not been reached yet. The question comes down to one of strength of the pinion rather than quietness, for with the continuous contact which spiral type bevels give, there seems to be no reason why an 8-tooth pinion will not run quietly in ratios up to 8 to 1. The only reason for using so few teeth in the pinion is to keep down the diameter of the gear. In this case the pinion must, of course, be made solid on the shaft.

Strength and Wear.

Perhaps the most satisfactory way to consider the strength and wear of spiral type bevels is by comparison with straight-tooth gears. For the same power transmitted, and other things being equal, the load on spiral teeth is greater than on straight teeth, because the spiral tooth must carry the additional thrust-load. This thrust-load varies with different angles of spiral, but assuming an angle of spiral of 30°, the total load on the tooth is about 15 per cent. greater than the corresponding tooth load for straight-tooth gears. To offset this extra load the spiral type gear has more teeth in contact at all times than the straight-tooth gear. Assuming that the spiral lead is such as to give an overlap equal at least to once the circular pitch, there will always be one more tooth in contact. While the contact of the extra tooth will not be full-length, still it will be more than enough to make up for a 15 per cent. increase in load. That is to say, spiral teeth, while they have a greater load to carry, have that load so distributed as to put less strain on each tooth. We have known of very severe tests of an electric car spiral type drive in which a nine-tooth six-pitch pinion running with a sixty-six-tooth gear with a face length of one and one-quarter inches, has stood up under repeated reversals of the motor when running at high speed. The total load, including three passengers, was about 4,000 pounds. The pinion was made of 5 per cent. nickel steel case-hardened and was, of course, solid with the shaft.

Referring again to the comparison of spiral type bevel gears and helical spur gears with parallel axes, it will be seen that inasmuch as the spiral type bevels have no more sliding action than straight-tooth bevels or spurs, there will be no more tendency to wear from the nature of the action. This can be seen from another point of view, by considering a spiral type tooth as made up from a straight tooth which has been cut into a number of sections normal to the tooth, the sections or laminae then being offset with respect to each other, or stepped, so as to conform to the spiral curve. Each section would then roll with the corresponding section of the mating tooth with the rolling action of straight-tooth gears. If the number of sections is increased the tooth approaches a spiral type tooth with a smooth curve, but the increase of sections does not introduce any more sliding action. A spiral type tooth may be considered as made up of an infinite number of such sections each infinitely thin, but the action will still be the same. Thus if there is no increase of sliding action, the only condition which will tend to increase the wear is the increased tooth load. The length of tooth measured along the spiral is, however, increased in the same proportion as the load itself, so that the unit pressure is the same as for straight teeth. It will thus be seen that spiral type teeth will show up at least as well as straight teeth as far as strength and wear are concerned.

Efficiency.

The efficiency of spiral type gears has been the subject of some discussion, but as soon as we look into this matter we find that spirals take their place in the high efficiency class alongside of straight-tooth bevels. Considering the action of these gears, we have already seen that there is no more sliding motion in the case of straight-tooth bevels. Consequently, there would be no loss of efficiency from this cause, as compared with straight teeth. One other feature which might cause a loss of power is the end-thrust of the pinion. It will be seen readily that if bearings provided to take this thrust have much friction loss, there will be just that much less power to apply to turning the wheels, and this loss would have to be charged up to the use of spiral bevels. That such loss might be considerable with bad bearings is apparent when we remember that the end-thrust of the pinion will in some cases be more than half as great as the transmitted tooth-load. The high efficiency of good bearings will, however, hold this loss down so low that in practical use it would be difficult to determine the amount of it. So much for the theory of efficiency. In practice, judging from all reports that have come from actual use, the change from straight-tooth to spiral type bevels can be made without any loss of power. As a general statement I would say that with proper mounting there will be no difference in efficiency between the two types of bevel gears.

As compared with the worm drive, the advantage as to efficiency is with spiral type bevels. It has been reported by a number of users that the efficiency of worm-drive axles is best at high speeds, and that there is considerable loss on the pick-up. As most worm drives are used on electric cars or

Digitized by Google

trucks, they are confined largely to town use, where there is sure to be a great deal of accelerating and retarding, working a considerable part of the time at a speed which gives a lower efficiency. A recent test of two electric cars the same in other respects, but one having a worm-drive axle and the other a spiral-type-bevel axle, gave results from which the engineers estimated that the worm-driven car would run 72 miles on a charge, while the bevel-driven car would run 95 miles. Great care was taken in this test to have the conditions exactly the same for the two cars. A 2 per cent. difference of efficiency in the two motors was reported by the manufacturers, but allowing for this the spiral-type-bevel axle would still show a mileage more than 25 per cent. greater than the worm axle. A coasting test was made of the same two cars, coming to a standstill at a certain point on a hill and allowing the cars to start under gravity, and run freely until they stopped. The bevel-driven car ran one and three-tenths times as far as the worm-driven car and at higher average speed.

Direction of Spiral and Thrust.

The direction or hand of spiral which it is best to use, and the thrust caused by spiral teeth are two points so closely related that they can be discussed best together. In speaking of direction of spiral it is usual to name the direction of the pair from that of the pinion, although it must be remembered that the hand of spiral of the gear is always the opposite of that of the pinion. For instance, if the pinion is cut with right-hand spiral and the mating gear with left-hand, the pair is called right-hand, and vice versa. The direction of spiral of the pinion is named the same as if it were a screw. As far as quietness is concerned, we are unable to discover any difference between right and left-hand spirals, from either theory or practice. With right-hand spiral the small end of the pinion rolls into contact first on forward drive, but it seems to make no difference which end is the first to engage. Large numbers of pairs have been produced with both directions of lead, and the results of quietness have been the same. In regard to efficiency, also, no difference could be found, except under special conditions of mounting.

The question of the amount and the direction of thrust is the most important factor in deciding the direction of spiral to be used. In speaking of thrust we recognize that the use of gears with spiral instead of straight teeth changes the loads on nearly all of the bearings of the differential assembly. We confine ourselves here to end-thrust of the pinion, because it is impossible to go into a complete analysis of all the bearing loads, and it is the pinion thrust that changes most with the introduction of spiral teeth and which requires the designer's attention most. Straight-tooth pinions are not without thrust. This thrust is, however, slight in amount with the usual driving gear ratios, is always in the same direction, and varies with the pressure angle and the pitch angle. It is one component of the total thrust of spiral bevel pinions. The thrust due to the curve of the tooth is much larger than that of straight-tooth pinions in usual automobile bevel-driving combinations, it varies in amount with the angle of spiral, and changes in direction with a change of the direction of spiral or a reversing of the drive. With a spiral angle of 30° the amount of spiral thrust alone is 64 per cent. of the transmitted tooth load. With 20° it is 40 per cent. With 25° it is 51 per cent. and with 35° 78 per cent. With a right-hand spiral this is a pull into the gear on forward drive, and a thrust back away from the gear on the reverse. With a left-hand spiral it is back out from the gear on the drive, and into the gear on the reverse. Combine with this the usual thrust of straight tooth pinions and we have as average results for ratios between 3 to 1 and 7 to 1 the following:

Angle of Spiral.....	20°	25°	30°	35°
Right-hand — forward	—.29	—.44	—.56	—.69
Right-hand — reverse	.41	.59	.72	.85
Left-hand — forward	.41	.59	.72	.85
Left-hand — reverse	—.29	—.44	—.56	—.69

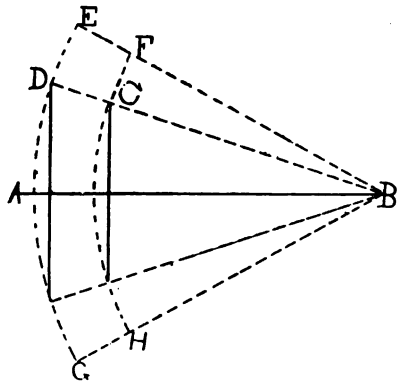
The decimals represent the thrust as a percentage of the transmitted tooth load. Positive values indicate thrust away from the gear; negative values indicate pull into the gear. The percentages given are to be used in connection with the tooth load, figured on the full pitch radius of the pinion at the large end. This is in order to facilitate computations in which these constants are used. For a tooth load figured on the mean pitch radius these constants would be reduced by one-eighth of their value. The load being that much greater, the final value of thrust would be the same.

From this it will be seen that for a 30° spiral angle, for instance, and a right-hand spiral the thrust for forward drive is 56 per cent. of the transmitted load, and tends to screw the pinion into the gear. For reverse drive it is 72 per cent., and thrusts the pinion back from the gear. With a left-hand spiral the thrust on forward drive is the larger figure and away from the gear; on reverse it is the smaller figure and into the gear. Here is where most designers decide the question of direction of spiral. If the bearing arrangement and general assembly of the pinion are such that there is little chance of end-movement, right-hand spiral can be used, making the thrust load under driving conditions less. If there is a chance that continued in-pull will cause play in the bearings, or if the bearings are not so well adapted for taking thrust in this direction, left-hand spiral will be chosen. Thus right-hand spiral favors the bearings for amount of load under forward drive, while left-hand puts on a heavier thrust load under forward drive. I have known of a right-hand spiral being chosen purely with reference to the amount of the load. The bearings selected would not stand the additional load of left-hand under constant use. Left-hand is frequently chose because bearings for taking an in-pull have usually been of less capacity than those taking an out-thrust, and left-hand spiral consequently involves less change in design. Whichever direction is chosen, arrangements must be made for taking the thrust in the opposite direction when backing up, though this is for comparatively little time and the loads are not so severe.

Other considerations affecting the choice of direction of spiral are lubrication, the question whether an in-pull is likely to loosen the pinion from its taper seat, and the possibility of a pinion having enough end-play to wedge into the gear and start cutting.

Amount of Spiral.

Theoretically, the amount or angle of spiral should be such as to give a lead equal to the circular pitch within the length of face. In practice the best results are obtained with somewhat more than this, and we recommend a lead of one and a quarter t



Digitized by Google

one and a half times the circular pitch. Tests made on automobile drives have shown that a lead of less than once the circular pitch, while giving fairly good results and reducing the thrust slightly, is only a compromise, and that it is much better to make provision for the slight extra thrust, and gain the advantage in quietness which a greater angle insures. Usually information as to the amount of spiral is wanted in terms of the angle. For four, four and a half and five diametral pitch and the usual face width, an angle in the neighborhood of 30 degrees will give the desired spiral lead. For a finer pitch or an extra long face, a smaller angle is sometimes satisfactory.

To sum up the case briefly for spiral type bevel gears, I find that they have the advantages of extreme quietness, large range of adjustment, accommodation to distortion of the housings, adaptability to high ratios, high efficiency and good wearing qualities. The only serious disadvantage is the thrust. We believe, however, that spiral type bevels have come to stay, and that designers will quickly learn to make any necessary changes in mounting in order to avail themselves of the many benefits which this type of drive affords.

Fitting New Clutch Leather.

From S. P. C., Rhode Island.—Noting in a recent issue that one of your readers was troubled with a faulty clutch of the cone type I am supplying a

sketch for making a pattern for a new leather which will cure his trouble. The plan is simple and easily followed. It is more reliable than attempting to use the old leather for a pattern.

Obtain a large sheet of fairly stiff paper and lay out the clutch to exact size. The faces must be at right angles. Draw a line through the center of the hub and parallel with it. This line is shown at A-B in the sketch. Use this point as a center and the distances from B to C and B to D as radii, and scribe the circles E G and F H. It is important that the distance from E to G equal the largest circumference of the cone so that the ends will come together true. It is best to cut the strip a trifle longer to allow for fitting.

Use good oak bark tanned sole leather or belting. Before fitting soak it in oil to make it pliable. Some will disagree with the writer and advocate water, but when water is used the leather shrinks and is apt to pull away from the rivets. In attaching leather, clamp one end to the cone, drill and countersink for rivets. Then pull the leather to the next set of holes. Repeat from one point of attachment. This will result in a tight fit. Drill but one set of holes at a time. After fitting the leather it should be trued up in a lather which can be done by any machinist at a slight cost. Unless familiar with the use of glass or sandpaper in scraping a leather facing, the novice had best let well enough alone and rely upon the machinist.

Employees' Clubs.

Addressing the entire office force and factory department heads of the Chalmers Motor Company recently, Hugh Chalmers advocated the founding of two clubs for the young men and women employees of the company.

"Prepare for the job ahead of you, because it is our idea to make promotions wherever possible from our own ranks," said Mr. Chalmers. "And by all means, think. It is far more necessary to run this plant by brain-power than by horse-power. Anyone can purchase electric current from the Edison Company, but if a central market for brains exists, we have yet to find it.

"To-day, the trouble with the average young man is that he expects to advance in the world through right of succession or because the boss likes him, or for some other mysterious reason. We lack the developed men, the men who have built up their abilities step by step, and are ready for increased responsibilities when called upon. We have reason to be thankful that the only real aristocracy in this country is one of brains and decency. And there is still plenty of demand for men of brains and initiative for the big jobs in every business.

"Our trouble, nowadays, is not in securing skilled labor, but in getting the men to fill the $4,000, $5,000 and $6,000 jobs.

"To the young women who earn a living in any department of our plant I want to emphasize the fortunate conditions under which you work. Caste has no place in the Chalmers organization and that applies with equal force to both men and women employees. If there is an appellation I despise, it is comprised in the two words 'working girl.' We owe the utmost respect and honor to every woman who earns her own livelihood."

That Carburetor Controller.

In the September issue there was published a short article in relation to a home-made carburetor control with an illustration. It has since appeared that this device is similar or identical to a patented carburetor control, made by Grace & Company, 3205 West Washington Street, Los Angeles, Cal. It supplies clean hot air to the fuel, acts as a decarbonizer and primer, provides a reliable air brake for the car, and the manufacturers are so confident it will do what is claimed for it that purchasers can have ten days in which to make a thorough test of the device on their engines and if it does not do as stated they may return it and the money will be promptly refunded. The price is $10.

The owner who is using vibrator coils will find that any excessive current consumption is due to excessive tension of the vibrator springs. The spring adjustment should be loosened until the motor begins to miss and then slowly tightened again until regular firing is resumed.

WHICH FORM OF COOLING?

An English Comparison of the Pump and Thermo-Syphon Systems.

Henry Sturmby in Motor, London.—Quite a considerable controversy has been carried on again lately over this ever-verdant question, but the disputants—as usual—do not appear to have "got any forrader." This is one of those questions in which the old adage applies, "He that's convinced against his will, is of the same opinion still," and as to just what are the real reasons for their respective contentions on opposite sides of the fence, well, "it all depends." It depends, in short, upon the ability with which the manufacturers of the cars used by the several disputants have carried out their work, for each participant in the wordy fray claims to speak from experience, in which, no doubt, he is right. It is like the old story of the men who argued and got to hot words about the color of the chamelion. Both were correct, so far as their observation went, but the conditions were different, and "circumstances alter cases."

So far as the question under consideration is concerned, both systems are good and perfectly satisfactory if intelligently carried out; but ever since my pioneer John o' Groats-Land's End drive, in 1898, when the only thing which "hung me up" on the road—and that three times—was the failure of the circulation pump to act, I have had more than a sneaking regard for the thermo-syphon system. In the words of a certain well-known advertisement, "It's so simple," when carried out properly, and that I know, for I have in my time built some hundreds of cars which not only had no pump, but were likewise minus a fan, in spite of the fact that the cars were geared, in some cases, as low as 7 to 1, and even lower on top gear; hence, whilst the engines were running fast, there was no rapid pace to force great quantities of fresh air over the radiators. Some of these cars worked perfectly satisfactorily on five and seven-mile hills, over grades running up to 1 in 6, and that, too, almost under the equator.

After that, no one can tell me that thermo-syphon cars cannot be built to work satisfactorily under all conditions and motoring, but they must be "built for the job" and not merely "altered over" makeshifts. A thermo-syphon car which is built for and will work perfectly satisfactorily upon British roads, in our English climate, will not be equally satisfactory if used over mountain roads in the tropics, although, if the car has been designed to work under the latter conditions, it can be depended upon to do good work and give no trouble in less severe circumstances; as a matter of fact, the same applies to both systems, for, unless a forced circulation car has been designed for the needful efficiency, it will fail when the conditions are beyond the normal, although giving perfect satisfaction otherwise.

The secret of success in thermo-syphon design is not merely the correct relative position of the engine to the radiator, which appeared to be the principal point in the recent argument. Whilst that has its importance, of course, as a factor towards success or otherwise, of far more importance are the two factors of area of radiating surface and cross area and freedom from longitudinal angularity of the water passages. If we keep always in mind the broad fact upon which the thermo-syphon system is based, viz., that hot water rises and cold water descends when forming part of the contents of a receptacle containing water at varying temperatures, we shall have no difficulty in arriving at a correct understanding of the way a circulatory system should be designed. In the first place, we have two containers, i. e., the radiator and engine water jacket, with tubular connections between them. To commence with, the water in both vessels is cold. Then the engine is started, and the heat absorbed by the cylinder walls is passed on to the water which surrounds them. We now have the water in one of the containers warmer than the rest of the fluid in the system, and the warmer portion of the water now wants to exercise its natural bent, i. e., to rise. If, then, the water jacket—in other words, the top of our engine—is the highest point in the system, it will be seen that the hot water, being already as high up in the system as it can go, cannot go any higher, and any movement of the water particles must take place downwards into the cold water below, or, still downwards, from the top of the engine to the lower radiator, which would be all against its natural inclination, and the result would be that very little movement would take place, and the water which was in immediate contact with the cylinder walls would just go on getting hotter and hotter till it boiled. Hence it follows that the top of our engine must be below the top of the radiator. Further, seeing that the object of our endeavor is to take away the water from around the engine directly it gets warm and before it gets hot, it follows that there will be little force in the upward flow; hence its path of movement must be made easy for it. If the water could rise vertically into an upper receptacle immediately over the engine, through a passage as large as the area of the water jacket itself, the slightest difference in temperature would cause movement, and rapid and practically even heating of the whole body of water would take place, just as it does in a kettle on the fire. This, then, is our ideal condition, and it consequently follows that our water passages must be as large as circumstances will permit. If we cannot get an overhead tank to flow into, we must get it high enough to give as upward a flow as possible to the water. It will readily be perceived, when these conditions are pointed out, that narrow ports, water passages and tortuous channels will check and hinder the flow of water under so light a pressure as the merely warmed water exerts, and anything which will check the flow of the current will keep the water longer in the jacket and the temperature will rise quicker.

It will also take little perception to follow that there must always be water in the highest part of the system. There being so little force behind the flow, the water cannot be forced upwards over an intervening space or division, so that the net result of all our efforts must be to allow the hot water quickly to rise to the highest point in the system.

But the effect of the radiator is rapidly to remove heat from the water, with the result (if we suppose the radiator is filled with hot water in the first place) that, as the heat is removed from the water by the radiator, it will tend to fall as it becomes colder. We must not forget that our upward and downward systems are interconnected, and if the hot water rises, it must have something else to take its place, otherwise it could not rise. It follows that the water in the bottom tank of the radiator is

Digitized by Google

colder, it will naturally flow into the bottom of the water jacket, to take the place of the hot water which is ascending; whilst, at the same time, the water from the upper tank, as it comes more and more into contact with the radiating surface provided for it, will, by becoming colder and heavier, as well as by being robbed of its supporting water, fall steadily to the bottom tank, and, in its turn, pass into the water jacket and recommence the cycle of operations. As we have to depend upon the natural flow of the water for circulation to take place, as the rate of that flow cannot be hurried, and as, moreover, the cooling of the water will depend upon the area of the radiating surface with which it is brought in contact, it follows (as I have already said) that the flow must be even and unrestricted, and if heavy service is required, i. e., if the engine is to be worked fast and hard, the area of the radiating surface must be large enough to deal with any volume of water and any amount of heat which the engine can put into it. If, therefore, it is found in practice that overheating of the engine or water takes place, it is proof in itself that either the passages are restricted and the free flow of the water held back, or else insufficient radiating surface has been provided for the severest conditions under which the engine will be worked.

A Broken Piston Ring.

The engine of a car became rather uncertain in starting, and its owner suspected and verified in turn the ignition, the carburetor, and the valves. The compression of each cylinder was tested in turn by feeling the resistance it offered to the rotation of the starting handle, and one cylinder proved to be almost compressionless; the engine would not start from a pull-up if the starting handle claw was so engaged that the weak cylinder was either the first or second resistance to be overcome. The exploded charges blew past the broken ring into the crankcase, and sent puffs of smoke out through the gauze cover of the crankcase breather. This usually occurs when faulty piston rings have perceptibly reduced the compression in a cylinder. In the case under notice, the pistons had but one ring each, and a piece of about ¼-in. in length had absolutely vanished from the ring of the erring cylinder, the two remaining pieces still lying in the groove. Such a puff of smoke from the crankcase breather is plainly determinative, and shows that the rings, and not the valves, are to blame.

The automatic spark advance not only does the work accurately but it does not forget. If a driver gives proper attention to steering the car, varying the throttle, applying the brakes and watching the road ahead, he will not have much time left to manipulate the spark lever or talk to passengers.

Painting an automobile so that it will look neat and workmanlike is an expert's job. You can easily improve the appearance by carefully washing the surface with warm water containing a little ammonia, and then giving it a coat of thin varnish.

Unusually rapid wear in the differential or transmission case often is due to grit in the grease. Carefully wipe the gritty dirt off the grease gun before inserting it.

BATTERY CONDITION.

How to Ascertain it and How to Care for the Electrolyte.

The frequent and careful inspection of the individual cells in a battery is necessary in order to detect any irregularity in their behavior. Many defects which ultimately develop are of slow but sure process, and inspection will not only reveal them in their early stages, but will prevent their becoming serious and a source of trouble and expense at a later period. In some batteries, for example, the separators used to keep the positive and negative elements from coming into contact with each other, and so short-circuiting, are not as efficient as they might be, with the result that small pieces of foreign matter—straw, dirt, displaced active material, etc. —occasionally bridge across the plates. Such "bridge" in course of time becomes coated over with sediment in the shape of small particles of reduced lead, or lead peroxide, and an electrical connection is thus established between the plates inside the cell. Internal discharging will now result and continue while the battery is at rest, the plates being unequally acted upon and a tendency to buckle established. Inspection of the cell would have revealed this condition, and the instant removal of the obstruction prevented the trouble from becoming serious. Short-circuiting of this description is avoided in the better batteries by the use of efficient separators, the plates being so packed that the cell becomes semi-solid, and, in this manner, rendered immune from short-circuit, and the effects of vibration.

Causes of failure and trouble are usually to be traced to quite simple occurrences, and it is only by inspection that such can be detected. Bad connections are a prolific source of trouble, while corroded terminals and faulty lid fittings lead to much inconvenience and expense. Other causes of trouble that may be mentioned, and, incidentally, avoided by inspection, are slipping separators, loss of electrolyte, irregular charging and discharging, broken and leaky containing boxes, and gradual sulphating.

It is necessary then for the motorist systematically to inspect his battery, and attention to the following points may render the detection of faults a comparatively easy matter.

A good idea of the state of a battery may be obtained by merely observing the color of the plates, and, in fact, there is really no better condition test. When a lead cell is first put in action, the negatives are a yellowish gray and the positives a dark brown, sometimes spotted with a whitish or reddish gray substance. If the first charge be continued for a sufficient period, the whitish material—the objectionable sulphate deposit—disappears, and the positives should then be dark red, chocolate or plum color, turning to a nearly black, wet slate color when fully charged.

After a small discharge, they will regain their former appearance. Any peculiarity in color, such as the appearance of a white deposit or a reddish scale, indicates want of attention, since the cell has been exhausted. Such cells should be brought back into condition by prolonged charging at a slow rate on a charging board.

When the cells are fully charged, the negative plates should assume a light metallic gray color, and, since the ideal condition to aim at is always to keep

Digitized by Google

the battery fully charged, the negatives should be of the color indicated and the positives a dark chocolate or plum color. The negatives, it should be noted, are always considerably lighter in color than the positives, and this hint may be of service in ascertaining the polarity if doubt should arise on this point.

It is quite possible to become an expert in regard to the color of the plates, for, by constant observation before and after a run, taken in conjunction with the voltmeter reading, the motorist will soon learn to appreciate whether the plates are of a good or bad color, and also to ascertain the amount of charge remaining in the battery.

Careful attention must be paid to the electrolyte, or the solution of sulphuric acid and water, which covers the plates. This solution is a mixture of two parts of specially pure sulphuric acid with about five parts of pure water, and 30 per cent. acid may be taken as the standard strength for ordinary purposes. Since the density of the acid varies with the condition of the battery, the state of the latter, as regards charge, may be ascertained by noting the density readings with a hydrometer. It is practically impossible to do this when the car is in motion, but some makers fit hydrometers to one of the cells of the lighting set at least, and then the density may be noted before and after a run and the necessary charging time calculated in this manner. For those who employ a battery only for lighting purposes, and also for the benefit of motorists making use of a charging board to keep their cells in condition, the following hints may be of service. When the cells are in good order, the density of the acid in each should be almost the same, and in a fully charged cell should be about 1.22. Above 1.2 indicates a battery more than half charged, while below 1.2 but above 1.18 indicates less than half charged. A reading below 1.18 means that the battery is exhausted and should be recharged immediately.

What is called a discharge indicator enables the driver to determine whether the cells require more or less charging during the run. The indicator consists of a tube containing four colored glass beads which rise when the acid attains various densities. Thus four beads up indicates too high a density and distilled water must be gently added and the cell agitated until only three are up. Three beads up mean that the cell is fully charged; two up that it is about two-thirds charged; one up about one-third charge running, while no beads up is a sign that the cell is exhausted and requires immediate recharging.

Exhausted Batteries.

For all ordinary lighting purposes it is very important to note that an exhausted battery is the result of lack of charge or waste of current, and if, after being fully charged, the cell is soon run down again, there is a fault somewhere, and the system must be examined. Should the electrolyte be spilled only acid of the same density as that in the cell at the time of refilling must be used. Do not add strong acid to an exhausted battery. It is best always to consult an experienced battery man before adding acid, but, if this cannot be done, use a hydrometer to obtain a mixture of the correct density. To replace loss due to evaporation, add pure distilled water at regular intervals, and always maintain the solution above the top of the plates. It is essential that pure or distilled water only be added and tap and boiler water must never be employed.

A clean non-metallic vessel is necessary for storing and handling water, and metallic funnels other than lead—enameled or otherwise—must not be used for electrolyte. Always replace and screw up the filling plugs after adding water to avoid loss of solution during the subsequent run, and examine a cell that requires an excessive water replacement. The cell will be found to be leaking, and, since a slow leak will cause loss of electrolyte and consequent sulphating, the cell should be repaired and replaced without delay. In cold weather add water just before running or charging to ensure mixing of the water and avoidance of freezing, and always wipe up spilled solution with cotton waste damped with ammonia water.

The Test Lamp.

A very convenient piece of apparatus for ascertaining the pressure, and, incidentally, the condition of a cell, is a small 2 volt lamp. By noting the brightness of the lamp as it is placed across each cell in turn an estimate of its condition may be found. A good voltmeter is also very desirable, and it will be found that the pressure of a cell rises to 2.4-2.6 volts near completion of the charge. When the voltmeter registers 15 volts for a 12 volt set, for example, the battery is fully charged. The discharging pressure when the lights are on will remain fairly constant at 2 volts per cell; that is, with a fully charged battery supplying the lamps with current and the car at rest, the pressure should be 12 volts for the six cell set.

It is of the utmost importance that the battery should never be discharged below 1.8 volts per cell or permanent sulphating will undoubtedly occur.

STARTING A STARTER.

Not Always Possible, But Usually This Is Due to Neglect.

The development of the self-starting device and its general adoption by auto makers and drivers have brought a new source of trouble to garage and repairmen. A self-starter that will not start either itself or the car is a vexation and the present short days with cool mornings has produced many. Of course the greater part are due to misuse, carelessness or ignorance, and a lot of drivers are learning how to start their self-starters when they will not start themselves.

Some of the trouble, it is true, is due to the fact that many thousands of the earlier types of the self-starter have been in use long enough to need repair parts and a general overhauling, but so much has come from simple "don't know" that the West Side Y. M. C. A. of New York City has put in a course on "Self-Starters," which is being largely patronized by garage and repairmen, as well as individual drivers.

"The self-starter is responsible for a lot of other troubles," said Mr. H. C. Brokaw, director of the school. "For instance, a car may be running along smoothly when the lights flash up and then go out. Mr. 'I Don't Know' starts in at the generator or the battery to trace each wire to locate the trouble. The trouble was that the lights had burned out. There was a loose connection at the battery or between the battery and generator and the entire current generated was sent over the light circuit, which quickly burned out the lamp filaments. Mr. 'Know

Digitized by Google

It' looks for the loose wire, puts in new bulbs and goes on without fear of the traffic cop.

"You see cars running every night with only part of the lights in order. Some have one headlight, some none and others have not even the tail light. Mr. 'Know It' understands that this means there is a wire disconnected, a burned out fuse or a short circuit. He has been taught methods of testing for each of the troubles and in a few minutes has the car all right.

"The average owner knows mighty little about his car and its mechanism. He listens to the salesman of a self-starter and lighting system, or of the car having it, and absorbs just enough of it to rise up later and trouble him. Many think the storage battery, for instance, is big enough to stand up under any conditions. They do a lot of starting and little running—which is when the battery is charged—and they do their running all at night, when all the lighting circuit is drawing upon the battery, and then wonder why the battery falls down. The conditions noted prevent the generator from recharging and sooner or later there is a discharged battery. He condemns the battery and starter system at once. The fact is there should be something else than the battery discharged.

"The ease of starting the car by the new method is a drawback in case of trouble. If a man had to get out and crank his car he'd be pretty likely to find out the cause of trouble before he had cranked it many times. With the self-starter, he sits still and generally cusses a lot before he decides to investigate.

"Students who come to us from garages tell us that self-starter troubles are the bane of the average garage. Some will not touch this class of repairs, but pass it on to the specialist.

"Troubles of self-starter systems, which suggest the remedy needed, may be summed up as: First, neglect of ordinary care. It isn't kept clean. Second, short circuit or open circuit, and lastly, worn, broken, or burned out parts, which would be discovered by a general overhauling at intervals. More and more chauffeurs and garage mechanics are being required to have this information."

Double Clutching.

Drivers of cars fitted with the quadrant or "straight through" type of gear change no doubt have found that the operation of changing from a high gear to a lower one is usually accompanied by a good deal of grating, which is caused by the two gear wheels that are required to mesh not running at the same speed. To enable the change to a lower gear to be made without noise, it is necessary to perform an intermediate operation of speeding up the clutch shaft to the number of revolutions required to drive the car at its existing speed when the lower gear is engaged. This is usually accomplished by the method known as "double clutching," which many people think can only be done on a car fitted with a gate change. It can, however, be performed just as well on a car having a quadrant or straight through change, for it will be found that if the lever be placed midway between any of the notches in the quadrant a free or neutral position will be obtained.

The process of "double-clutching" on a car with a gear change of this description resolves itself into the following operations: Press the clutch out and place the lever between the notch it has just left and the one next to it, with which it is to engage; then let in the clutch and accelerate the engine slightly, disengage the clutch and move the gear lever without hesitation, into the next notch, thus engaging the next lower gear. After a little practice, it will be found quite easy to change the gear silently in this way. It should be kept in mind that the clutch pedal should not be depressed so much as to bring the clutch stop into action when changing down to a lower gear or noise will certainly occur. The movements should not be performed hurriedly, but, on the other hand, rather more time should be taken in effecting the gear change than would be taken if the ordinary method of changing were being employed.

Difficult Oiling.

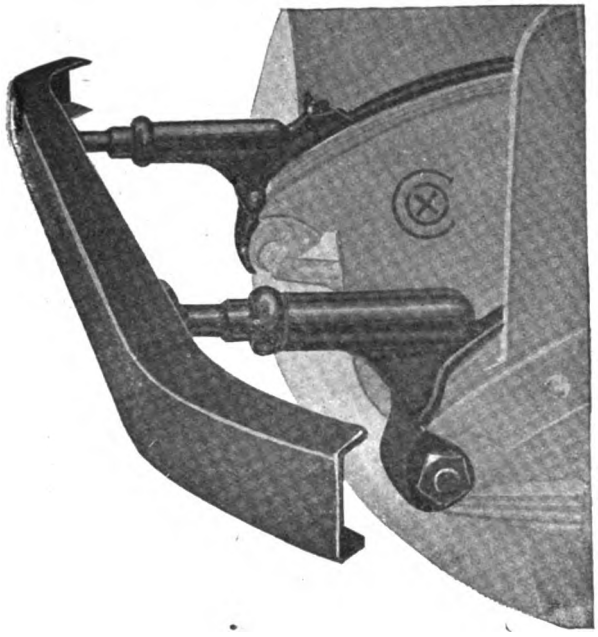
The manufacturer and the experienced motorist will blame ignorant owners for their neglect to fill grease cups and to oil up generally. Yet some of the blame should go to the manufacturers who continue to turn out cars that have grease cups or oil holes all over them, every one of which needs periodical attention separately, and many of which can only be got at with very considerable difficulty, and a great deal of dirt and discomfort; in fact, the only way in which many cars can be at all easily dealt with so far as the greasing of the universal joints is concerned, the oiling of the brake gear, the replacement of the speedometer belt or oiling of the speedometer spindle, is by means of a pit, though every manufacturer has for many years been assuring us that the modern car need have no pit. This proud assertion is literally true, because if a person does not mind crawling under a car and rolling about in very contorted positions, varying the performance by climbing into the car and diving through floor boards he may indeed dispense with a pit.

Faulty Valve Cap Joints.

It would surprise many motorists to find the great loss of compression due to faulty valve cap joints. To test for leaks apply soapsuds as being cleaner than oil, and the difficulty in making them fairly gas tight must be experienced to be appreciated. After following the usual course, thoroughly cleaning the seating, etc., apply a fairly liberal dose of gold size on both sides of the copper and asbestos washer, but even this often fails to remedy the trouble. Perhaps someone can give a better "tip."

Do not forget that copper attempted to be ground in a carborundum wheel always clogs. You can avoid this by rubbing a little tallow on the copper. This will not interfere with the cutting of the wheel.

Some mix one ounce of picric acid or ether to five gallons of gasoline for use as a priming fuel only. It gives a more forceful explosion than gasoline alone, but should not be used after the engine has started.



Valve trouble is produced when carbon forms around the edge of the valve, forming a hard crust that prevents the valve sitting tight.

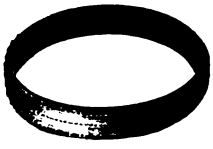
NEW AND INTERESTING THINGS IN MOTORDOM

A New Bumper.



The Cox Brass Mfg. Co. of Albany, N. Y., offers a new specially designed bumper for the 1916 Cadillac. This car differs from other models and makes in several ways and requires a special type bumper. As shown in the illustration, the bumper is attached by the brackets that go over the nose of the springs. No additional holes need be drilled. The two bolts that hold the splasher and mud guard to the frame are replaced by two longer ones supplied by the Cox Company. These anchor frame, mud guard, splasher and bracket securely. Where the bracket goes over the nose of the frame it is held by a special lock nut which fastens on the regular shackle bolt which is supplied. The bumpers are made in the channel, diamond and round types. Each type is furnished in either nickel or black enamel and retail prices range from $10 to $6.50.

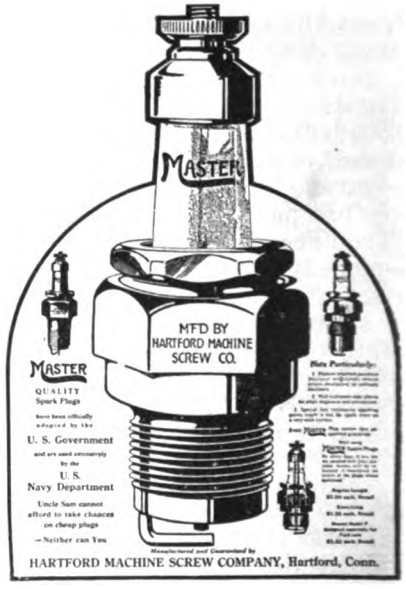
A Special Bumper for Cadillac Cars.

A No-stretch Ford Fan Belt.

A Ford fan belt that will appeal strongly to all users of Ford automobiles has recently been put on the market by the Leather Tire Goods Company of Niagara Falls, N. Y. This belt consists of a ply of strong non-stretching fabric, having a ply of leather sewed on the face of it where it comes in contact with the pulleys. The leather is treated by a special process that makes it always hug the pulleys perfectly, and, since the fabric prevents stretching, the belt seldom or never requires adjustment. On account of the high speed at which Ford fans run, there is unusual strain on the belt, and a belt like this, which will not stretch or slip, is especially valuable. The price of the belt is 40 cents each, and they will be sent postpaid by the makers to any part of the United States or Canada on receipt of price, or three belts will be sent for $1.

Ford Fan Belt.

New Delivery Body for Ford Cars.



A new delivery body especially designed for Ford cars has been brought out by "Angier's," Streator, Ill. This is an open type body with flare-boards and box seat, and it fits any Ford chassis. It has a length over all of 103 inches, an extreme width of 43 inches, height of seat 16 inches, size floorboards front of seat 22x33 inches, height of body 8 inches, over flareboards 14 inches, loading space 65½x33 inches. This body is of excellent quality. It is made of carefully selected lumber and built on oak sills. It comes knocked down, but can be put together by any one in an hour. It is finished in one coat of prime, and weighs about 180 pounds. These bodies are sold only to jobbers and dealers, and they are not sold at retail under any circumstances. Contracts must cover at least 10 bodies to have any order filled, as the prices are based on a large output. Dealers' price will be about $18.50 each, with a liberal cash discount, and jobbers are urged to write for prices in lots of 25, as these prices will be gladly quoted on application. Nearly all dealers have some demand for delivery bodies for Ford cars, and this affords an excellent opportunity for a good profit on this line of goods.

An Unusually Complete Catalogue.

We acknowledge receipt of the new catalogue for 1916 which has recently been brought out by the Gemco Manufacturing Company of Milwaukee, Wis. This catalogue contains a surprisingly large list of accessories for all cars, and an especially comprehensive list of accessories particularly made for the Ford car. We understand that this catalogue will be sent to any dealer or car owner free of charge on application, and no doubt many of our readers will want to send for it. It is a profusely illustrated book of 64 pages, and will be very valuable for reference to any car owner or dealer.

A Neat Display Stand.

The Hartford Machine Screw Company, Hartford, Conn., is offering to dealers handling their Master Spark Plugs a very attractive display stand. Particularly noticeable is the Mammoth plug, which can be seen for a long distance. The stand is 20 inches high, in three colors, with a brilliant red background, and the plugs in silver and blue. This stand should make an attractive piece of advertising matter for any dealer and is most certain to attract the attention of a prospective purchaser of spark plugs when he enters a dealer's store. The stand is so arranged that it may be set on a counter or can be hung up in a conspicuous place or used in connection with a window display. It calls attention to the fact that Master Plugs have been adopted by the United States government and are used extensively in the United States Navy department and also points out the principle features of excellence of the Master Spark Plugs, such as massive imported porcelain insulator, ample room for expansion and contraction, low resistance sparking points and the unqualified Master guarantee. It is a very unique and effective piece of advertising matter and dealers interested should apply for their stand at once, as the supply is readily being depleted. Master spark plugs have enjoyed a larger popularity in 1915 than ever before, and it is rumored that an announcement of great interest to the trade is to be made in connection with the 1916 models.

For Spark Plug Display.

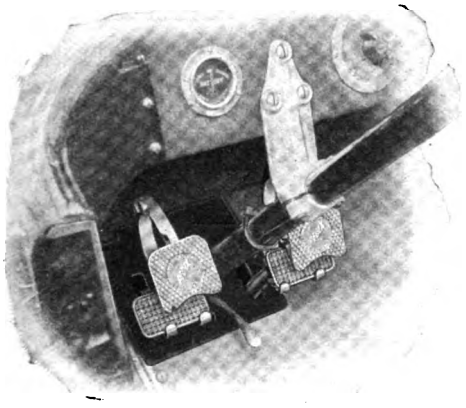
Fire Fly Light.



This is a most convenient automobile trouble finder's light. It consists of one dry battery and two incandescent lights with mirror reflector. The handle projects from a fibrous disc with a switch by which one light may be flashed separately or two together. It is not a spot light, but a light that will light up a

whole room light enough to read by. The U clip on the bottom of the illustration is to screw to the floor back of the driver so that he can pull the lantern from the U clip to measure the gasoline or read sign boards. The light is marketed by Geo. K. Burleigh, Penacook, N. H., at $2 each.

A New Pedal Extension.

The American Car Accessories Company has brought out a new pedal extension called the Pedex, which can be

A New Extension Pedal.

attached to the permanent pedals of any car and adjusted to fit any reach. By the use of this device two or more persons of different height can drive the same car, and the foot of the driver will always be in the most convenient and comfortable position. The Pedex only costs $5 a pair f. o. b. New York, and in sending your inquiry and orders for this article address American Car Accessories Company, Department E, 30 Church Street, New York City.

Peerless Goggles.

Max G. Cohn & Co., Inc., 19 Madison Avenue, New York, is offering a line of goggles under the name of Peerless, and a special feature is the use of an adjustable, non-breakable temple piece, made of Zylonite. This substance is flexible and allows of the temple being made into any shape merely by bending. The eye-pieces of the goggles are two inches in diameter.

Thermite Anti-Freeze.

This is an anti-freeze solution, which is said by the maker, the Northwestern Chemical Co., Marietta, Ohio, to freeze at seventy degrees below zero. When mixed with the same volume of water, the resultant solution is said to freeze at sixteen degrees below zero. Evaporation is said to be slight, and the maker claims the cooling system is not injured by its use.

The Powell Appliances.

The William Powell Company of Cincinnati, Ohio, make a large number of appliances for commercial vehicles and gasoline and oil engines. Their reputation for quality is always maintained by superior manufacturing facilities and an exacting and vigorous system of shop inspection, which enables them to fill every requirement. The Powell service anticipates every need of the consumer. The Powell methods insure the quality and uniformity of their products.

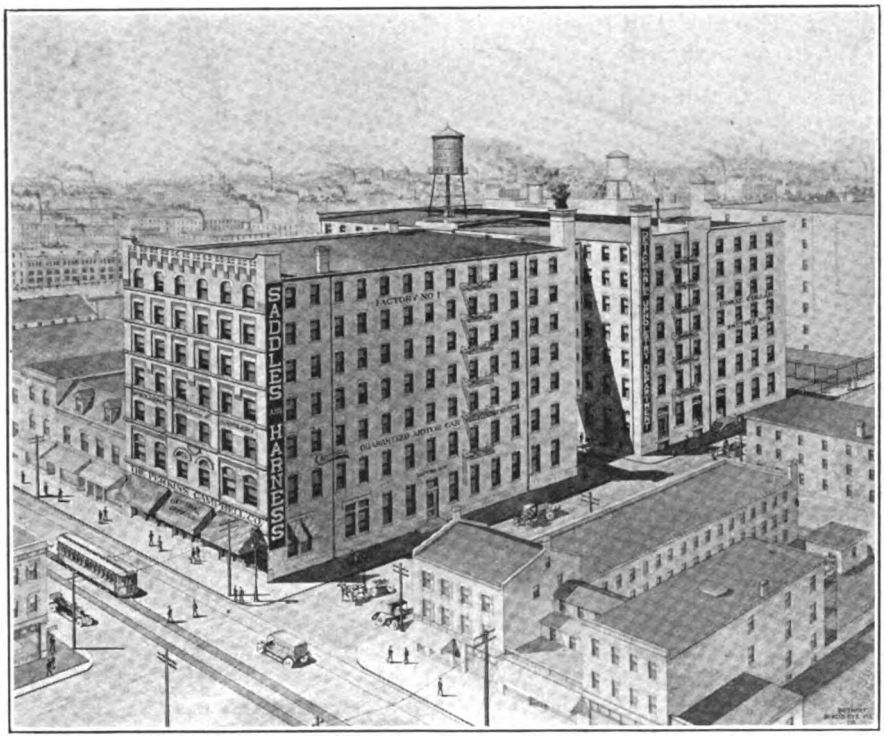
Heating the Garage in Winter.

The Scientific Heater Company, Power Avenue, Cleveland, Ohio, has perfected a heater that will appeal to the motorist owning or leasing an unheated building. One of its qualities is that it requires no alteration of the garage building, such as installing boilers, etc., the fuel utilized being artificial or natural gas. Owing to the fact that there is more or less gasoline vapor present in the garage it is not practical to utilize any heating arrangement having an exposed or naked flame, as it is well known that the fumes of the fuel, being heavier than air, are present in clouds of vapor near the floor. The Scientific design embodies the same safety principles as the miner's lamp. It heats by the principle of air circulation; that is, it causes the air in the garage to circulate through the heater, up one side of the building, down the other, across the floor and again through the heater. The manufacturers state that the system is easily installed, the only expense being that of piping to the city mains. Exhaustive meter tests have proven that it is possible to operate the Scientific system at a cost of a few cents a day. The accompanying illustration depicts the single type of heater, No. 700 size. This model will heat the ordinary two-machine garage comfortably during zero weather. The heater is built in three sizes for heating garages, 18x20 feet up to 26x36 feet. In public garages as many heaters can be installed as is necessary to cover the radiation. The 1916 model Scientific incorporates a great many new features over past seasons. Important among these is a self-lighter which eliminates the dangerous use of matches inside of the garage. It will undoubtedly be a great factor in decreasing gas bills. Another improvement is the double perforated metal screen. This is the safety screen and is of a more substantial construction than that used in the past. A brush located between the two screens makes it possible to clean the heater easily. The heater's construction is of the most rigid design and incorporates only the highest grade materials and workmanship. It is absolutely fool proof. The company has issued a number of attractive pieces of literature covering the heater which they

Scientific Safety Garage Heater.

state they will be glad to mail to any interested motorists. Their booklet, "Winter Motoring," is especially thorough in the way in which it treats upon garage heating. For a copy, address as above.

Disco Increases Capitalization.



The Disco Electric Starter Company, Detroit, has increased its capital stock from $60,000 to $100,000, the extra $40,000 being subscribed by the present stockholders. It is said that still another increase is to be made to enable the company to build a larger factory and install the special machinery necessary for a large production.

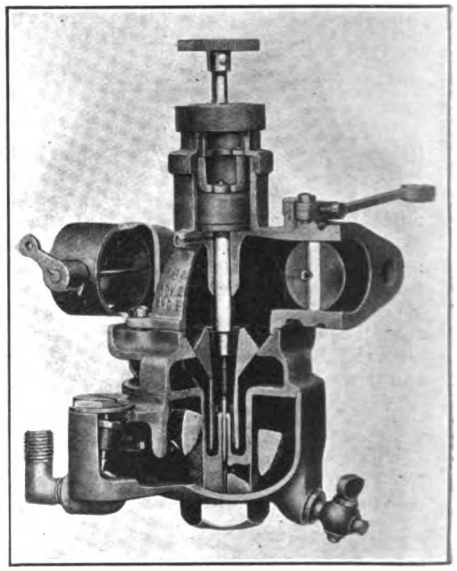
A Large Manufacturing Plant.

A large majority of our readers are already familiar with the line of detachable upholstery for automobiles which has been placed upon the market by the Perkins-Campbell Company, 628 Broadway, Cincinnati, Ohio. Some may not realize, however, that all the large variety of goods marketed by this house

Perkins-Campbell Factory.

is made in their own factory in Cincinnati, and we therefore take pleasure in showing in connection with this article an excellent picture of their big plant which is busy up to its full capacity in the manufacture of automobile upholstery and other similar goods. Readers are urged to write direct to this manufacturer for sample and prices, also catalogue of other high-grade guaranteed motor car accessories. This literature will be found very interesting and it ought to be in the hands of every car owner and dealer.

The Carburetor With a Thousand Jets.



The Diamond Carburetor Co., Inc., of Colgate and Mercer Streets, Jersey City, N. J., has for the past nine months been putting out a carburetor which is specially designed for Ford cars. It runs the car smoothly and economically and can be attached to the Ford motor in about a half hour without extra manifold or fittings, and in which all the parts furnished with the Ford car, including the hot air pipe, dash adjustment, air shutter wire, throttle connection, etc., may be used without alterations. The Diamond carburetor for Ford cars illustrated herewith is but one of a line of carburetors which this company is bringing out for quantity built cars, so designed that they can be easily and quickly attached in the place of the present standard equipment. It is of the metering-pin type in which the air valve carries a fuel metering valve. It is called "The Carburetor of a Thousand Jets" because for every infinitesimal rise of the air valve there is a change in the opening of the fuel valve which has been worked out to be correct for the corresponding air opening. There is one moving part which controls the primary air, the auxiliary air and the fuel nozzle. The primary air is variable and admitted through the center of the valve past the nozzle, and the auxiliary air around the outside of the valve. The valve has considerable movement and the metering pin is of considerable length with the self-aligning point. The bearing part of the moving member is in an upper air-dash chamber. It is suspended as it were from the top and the bearing is not exposed to dust and abrasive matter passing through the carburetor. The air-dash plunger is made of solid graphite and self-lubricating.

There is but one adjustment which affects all speeds alike, once adjusted for high speed it is correct for low speed. The proper ratio of fuel and air has been worked out in the taper of the air and fuel valves. The adjustment affects the mixture throughout its entire range. The adjustment can be made from the dash or steering wheel by which the carburetor is adjusted while the engine is running without interfering with its operation. The carburetor can therefore be instantly adapted to any condition of temperature or power requirements. When the motor is cold the mixture may be enriched, and as the engine warms up the mixture should be cut down as much as possible. This company claims between 20 and 35 miles to the gallon on Ford cars.

The Ford type of this instrument has proven unusually pleasing in its performance, the acceleration is always smooth and the operation of the car is velvety. With the high gear clutch engaged the motor operates easily and for considerable distances when throttled down to a speed of five miles per hour, invariably accelerating without perceptible loading, missing or bucking. Owing to the automatic operation of the single part, this effect is secured independent of the rate of throttle movement, so that the instrument exhibits the attractive property of causing the engine to pick up gradually and smoothly, even when the throttle is suddenly wrenched wide open.

There are over six hundred of these instruments in operation on Ford cars since April of this year, when deliveries first commenced. Arrangements have been made with distributors in the following cities and states: New York, Chicago, Boston, Newark, N. J., Worcester, Mass.; New Haven, Conn.; Providence and the state of Rhode Island. The list price of the Ford model is $12.50. The other one-inch Diamond carburetor models which are suitable for the Overland, Oakland, Baby Olds, Buick and Maxwell cars list for $15.00. These models are made with top outlets, both in straight and cross flanges.

Ernest Charles Cox, president and general manager of the Diamond Carburetor Co., Inc., since its organization,

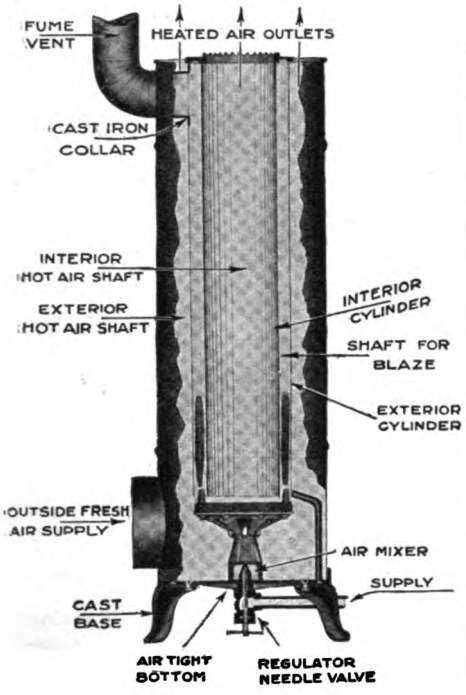
New Carburetor for Ford Cars.

has long been associated with the automobile industry in various capacities, devoting considerable time to the carburetor business. The instrument in its various forms is the invention of Carl F. Schulz, who is the company's engineer.

Ford Buys Saxon Stock.

Harry W. Ford, president of the Saxon Motor Company, has purchased all the stock which Hugh Chalmers, president of the Chalmers Motor Company, held in the Saxon company. The deal involves a cash transaction of half a million dollars and makes Mr. Ford the largest individual stockholder in the Saxon company.

"A Sure Start."



Under the above title the Electric Storage Battery Company of Philadelphia, Pa., has put out a booklet which is a discussion in most unusual form of the subject of starting batteries and springs, and the method of caring for the battery.

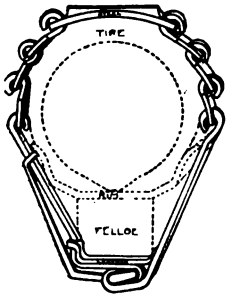
The Reo Garage Heater.

Many of our readers know what it is to have trouble with their cars in the extreme cold weather. Great damage is often done by the freezing and bursting of radiators, and the cracking of water jackets due to freezing. Sometimes there



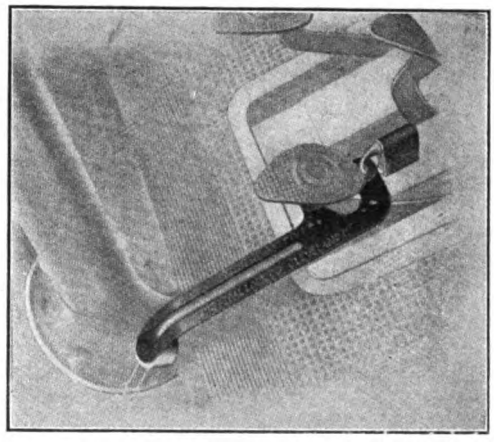
A Fine Garage Heater.

is ice in the batteries which also makes trouble, and also gumming of the oil in the working parts. All these troubles may be remedied by installing a good gas heater in your garage, and we illustrate herewith an excellent type of heater which is manufactured by the Edwards Manufacturing Company, 423-473 Eggleston Avenue, Cincinnati, Ohio. Now is the time to purchase heaters, and no doubt many of our readers will be glad to correspond with this company and get their prices. This is an excellent article for the dealer to handle at this season of the year.

Anti-Skid Mud Chain and Blowout Clasp

Illustrated herewith is a sketch of an anti-skid clasp which by a cam arrangement is clasped around the tire tight so that it presses into the rubber and sticks tight to it. Can be put on with one hand in a jiffey. Don't need to get off in the

Anti-Skid Tire Clasp.

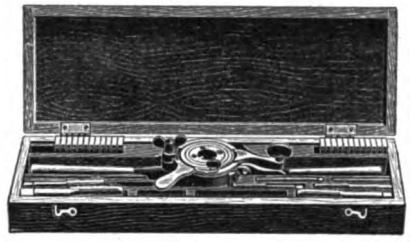


mud; just stand on the runboard. Place the chain over the tire, hooking the cam, and press the lever down; this tightens it on and locks it. Intended for use in mudholes. For instance, if the hind wheel is in the mud and slips around, one or more of these can be put on in a minute. These can also be put on over a swell or blowout in a tire and will push it down tight and hold any old blowout. One of these will generally take a wheel out of a slippery place, but for continuous running over a muddy road six at equal intervals are advisable to keep the car from slipping sidewise. Did your hind wheels ever slip around in the mud and your car stand still, and did you hunt up some boards and pull grass and shovel dirt and try to jack your car up to get chains on? These chains go on without raising the wheel, and quicker than you can say d——.

It is made from flat steel ⅛ of an inch thick, the tread plate being two inches wide and the links 1¼ inches wide. The cam is on one end and a hook on the other end which the cam hooks into when placed together. A piece of leather is placed on the steel band where it comes in contact with the felloe to keep from marring the varnish. The tread plate is corrugated to keep from slipping and has a surface of four or five square inches pressing flat against the tire and cannot roll like a common twisted chain and will not chatter the hind axle when running on pavement. The hooks on the sides will hold the wheel from slipping as soon as they sink in the mud—it cuts the rut wider instead of sinking the wheel deeper. To take them off, just jerk the little lever and off they come.

This device is manufactured by the Kimball Tire Case Company, Council Bluffs, Iowa, to whom all correspondence should be addressed.

Pedal Lock for Ford Cars.



We illustrate herewith a pedal lock for Ford cars which is manufactured by the Commercial Manufacturing Company, Commercial building, Cleveland, Ohio. By regrettable error in our October issue an article was published relating to this lock and the wrong illustration was used, so that our readers would gain a very incorrect idea as to the appearance and method of this device. We are glad to make full correction at this time. The device is an excellent one and ought to appeal to a great many of our readers who own Ford cars or deal in them. This is a positive lock which makes it impossible for anyone to start the car, and the same manufacturers also make the locks for larger cars, such as the Overland, Studebaker, Oakland, Jackson, Cole and various others, but, of course, the Ford lock will fit no other make of cars. Correspondence is invited both from car owners and dealers. For full particulars write direct to the manufacturers.

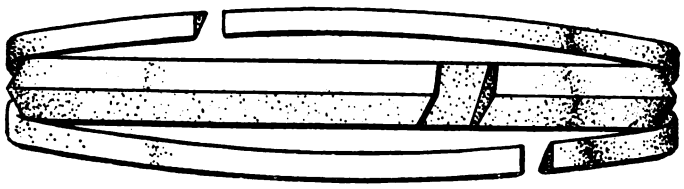
A New Pedal Lock.

Automobile Screw Plates.

Screw-plates which thread eleven A. L. A. M. standard sizes of bolts and adjust perfectly for re-threading worn bolts to any size desired are made by the Oster Manufacturing Company, Cleveland, Ohio. A feature of these screw-plates is their simplicity of operation. The dies can be quickly adjusted for a tight or loose fitting nut or for any

Screw Plate Case.

variation, by one movement of the cam-handle. After the thread is cut the dies are instantly opened. There is no backing off over the finished threads. To change the dies it is necessary merely to release the clamps and throw the cam the full limit of travel, then remove and replace. A simple movement of the cam causes the self-centering guides to grip the bolt and hold it fast; one set of guides adjusts for all sizes the tool threads. Two cuts may be taken when the operator chooses to do so. The superior accuracy and lasting qualities of this screw-plate together with the ready adaptability described above recommend it to automobile men as specially suited to the precise and rapid operations necessary in a garage. Catalogue No. 20 describing these screw-plates may be secured free by writing The Oster Manufacturing Company, 2102 East 61st Street, Cleveland, Ohio.



Extension for Chalmers Plant.

Contracts have been let for a four-story addition to the plant of the Chalmers Motor Company, Detroit. It will be 60 by 200 feet, and will provide 50,000 additional square feet of floor space. It will contain an extension of the machine shop and stock room.

The R. & M. Conform Piston Ring.

The manufacturers of this piston ring make the point that it is mechanically right, and therefore will give 100 per cent. efficiency. It is claimed that it will also give more power to the motor with less gas. It is a scientific fact that piston rings give the best satisfaction which permit the least loss of compression and which give the least loss of power from friction, and the manufacturers state that this piston ring is guaranteed to do this; also to cut the

An Efficient Piston Ring.

cost of maintenance by reducing gasoline and oil consumption, and greatly eliminating carbonization and spark plug troubles. The illustration will give a clear idea of the construction of this ring. When the rings are compressed in the cylinder, the joints are concealed. Jobbers and dealers are wanted to handle this piston ring in every city. Whether you are a car owner or a dealer you are invited to write for prices and full particulars direct to the distributors, the Superior Auto Parts Company, 938 Fort Wayne Avenue, Indianapolis, Ind.

Gould Storage Batteries on Standard Cars.

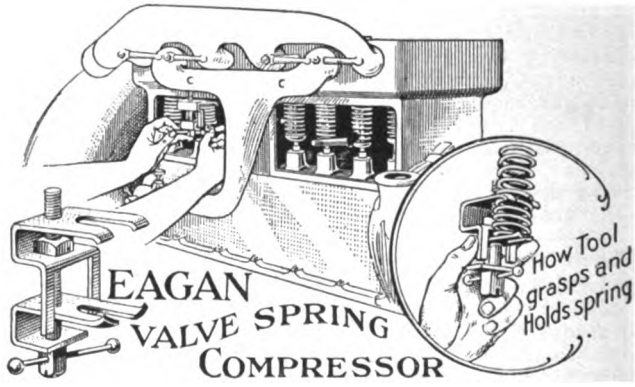
The Gould storage batteries are used as standard equipment on a great many automobiles and, among others, this battery has been adopted as regular equipment by the Standard Steel Car Company of Pittsburgh, Pa., and agents for the Standard car are urged to write to the Gould Storage Battery Company, 30 East 42nd Street, New York, for list of service stations where these batteries are re-charged. Dealers in automobile accessories, garage owners and electrical dealers should also get full particulars as to the agency plan which is followed in marketing these batteries.

A Vigilance Committee on Advertising.

Many of our readers are undoubtedly familiar with the Advertising Men's League of New York City, which has its headquarters at No. 200 Fifth Avenue, New York City. The Vigilance Committee of this league has organized a movement the object of which is to raise the standard of practice in all advertising, and to prevent fraudulent advertising, so far as possible. At the regular meeting of the New York Trade Press Association held in New York City October 22, 1915, the following resolutions were unanimously adopted:

Whereas, the Trade Press Association has for one of its purposes the systematic promotion of honest advertising and the discouragement of dishonest advertising, and

Whereas we believe the organization and plan of the Vigilance Committee of the Advertising Men's League of New York, known as the Advertising Protective Bureau, will raise the standard of practice in all advertising and minimize the practice of fraudulent advertising;



Be it resolved that the Trade Press Association endorses the objects and purposes of the Advertising Protective Bureau and its members do hereby agree to individually give the bureau their unqualified support and active co-operation, and

Be it resolved that the secretary be instructed to advise the Advertising Protective Bureau accordingly.

All publishers and reputable advertisers should share the opinion of the New York Trade Press Association, that the work of this Vigilance Committee ought to be warmly supported, not only by publishers, but by advertisers throughout the greater city.

Eagan Valve Spring Compressor.

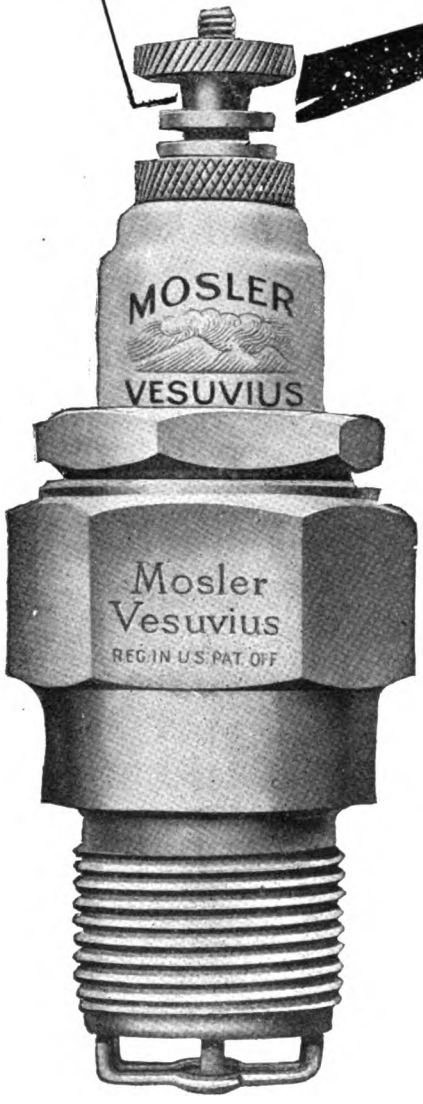
This is a simple device as illustrated herewith which is especially intended for removing the springs from Ford valves or any other small car. With this tool any handy person can remove valves for grinding without being obliged to remove manifold, exhaust or carburetor. It is not a cheap cast-iron affair, but is made out of the best sheet steel, properly hardened and absolutely guaranteed, as it is practically indestructible. The method of working is clearly shown in the accompanying illustration. Dealers or car owners who may be interested should write for full information to Fred Gabriel's Auto Supply Company, general distributors, 1165 Bedford Avenue, Brooklyn, N. Y.

Movement to Protect Accessory Dealers.

An interesting announcement is the one just made by Mr. E. H. Schwab on behalf of the Silvex Company, manufacturers of the Bethlehem five-point spark plugs. "This concern," stated Mr. Schwab, "has decided to take immediate and drastic action in regard to the cutting of prices on the Bethlehem spark plug by the so-called mail-order and cut-price houses with a view of giving to the legitimate jobber and dealer in automobile accessories the protection to which they are entitled. Having created a tremendous demand for Bethlehem plugs by an insistent and expensive compaign of advertising, the Silvex Company is in a position to understand the havoc raised by these cut-price houses in so far as the business of the legitimate dealer is concerned."

Mr. Schwab has stated on numerous occasions that it is his belief that a manufacturer of automobile supplies is in no position to expect the co-operation and support of the legitimate jobber and dealer, when, at the same time, he sells either directly or indirectly to a cut-price house wth the full knowledge of the fact that such house will inevitably cut prices in order to secure business on the product.

An idea of the importance of this announcement can be obtained when one knows that Mr. Schwab has stated that the adoption of this policy means the voluntary surrendering of a business of more than 100,000 Bethlehem plugs per year, which can be secured without difficulty from cut-price houses. "The Silvex Company," further states Mr. Schwab, "invites suggestions from all legitimate dealers as to further stands that may be taken to give them complete protection."



Unico Bodies for Ford Cars.

These are manufactured in limousine and coupe top styles by the Unit Construction Co., 125 South 31st Street, Philadelphia, Pa., at a price of $75 and upwards. These tops are of the best body construction with wood frame, metal panels, glass sash, minimum steel and hardwood, and maximum glass. Strength is combined with light weight. The tops are also finished in the best manner, as they have a seven coat exterior coach finish, and the interior has a full upholstered lining. Materials of the highest quality is used in every detail of these tops. The adjustable windows are set in rubber. The tops are also provided with electric dome lights, and sedan doors, with all necessary fixtures complete for quick attachment. A most liberal proposition is made to agents and dealers, and these tops should not be confounded with the many cheap articles of this character on the market. Exclusive agencies will be placed in every town, county, and city, east of the Mississippi River, and dealers who wish to secure agencies should act quickly, as territory is being closed daily. Write, wire, or call on this company at the address named for complete information and details.

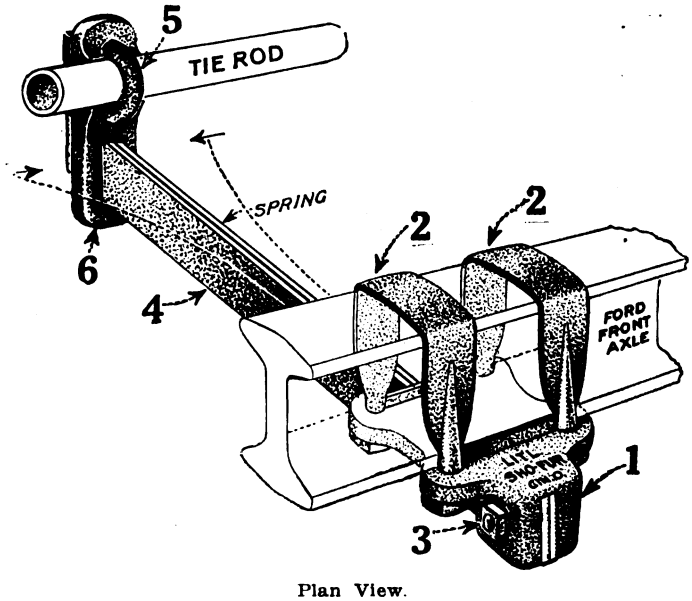
The Herz Ford Pro-mo-tor.

This is a new spark plug especially designed for the Ford car. The illustration will give an excellent idea of the novel features which have been incorporated in this spark plug. The plug is completely protected against leakage, moisture, dirt or slush by the hood and the new patented terminal. The hood is made of stone and completely encloses and protects the inner insulation. It has

Plan View.

a copper rim on the open end which makes it almost unbreakable. The upper end is formed so as to provide for the entry of the cable. A peculiarly shaped rubber cap fits over the top of the hood, and with the insulated top nut forms the cable connection. The claims made for this plug are that it is absolutely self-cleaning, soot-proof, waterproof, dust-proof and shock-proof. The workmanship and material are of such exceptionally high character that only the large quantity of production makes it possible to produce such value at the price, which is only $1 postpaid, or at all dealers. It is manufactured by Herz & Co., 245 West 55th Street, New York, and correspondence is invited from dealers, repairmen, garage owners or car owners.

The Lion Trailer.



The attention of motorists throughout the country has been directed recently in the strongest way to the idea of attaching trailers to pleasure cars and by this means getting all the advantage of delivery wagon use from an ordinary car. The Lion Economy Trailer has been manufactured for this purpose, and it can be attached or detached to any car in an instant. It is a great convenience for farmers, dairy men, grocers, carpenters, merchants, hotels, contractors and many others, and it is claimed that the weight of material carried in this way consumes less power and gasoline than to carry the same load on the car. Distributors, dealers and agents for the Lion Trailer are wanted throughout the country, and exclusive territory contracts are now being made as rapidly as possible. The Lion Trailer offers a new, broad and profitable field for live representatives everywhere and dealers or any others who are interested in an agency for this article should write at once, mentioning the territory wanted. Address all inquiries to the Lion Buggy Company, Department A. R., Cincinnati, Ohio.

The New York Automobile Show.

According to present indications the coming automobile show in Grand Central Palace, New York City, will be the greatest of its kind ever held. The show will open on New Year's eve, December 31, 1915, and continue until January 8, 1916. It will be, as usual, under the auspices of the National Automobile Chamber of Commerce, Inc., and S. A. Miles, as in years past, will act as manager, which in itself is a sufficient assurance that the show will be skillfully and successfully conducted. The Chicago show, under the same management, will be held at the Coliseum and First Regiment Armory, from January 22nd to 29th, 1916, inclusive.

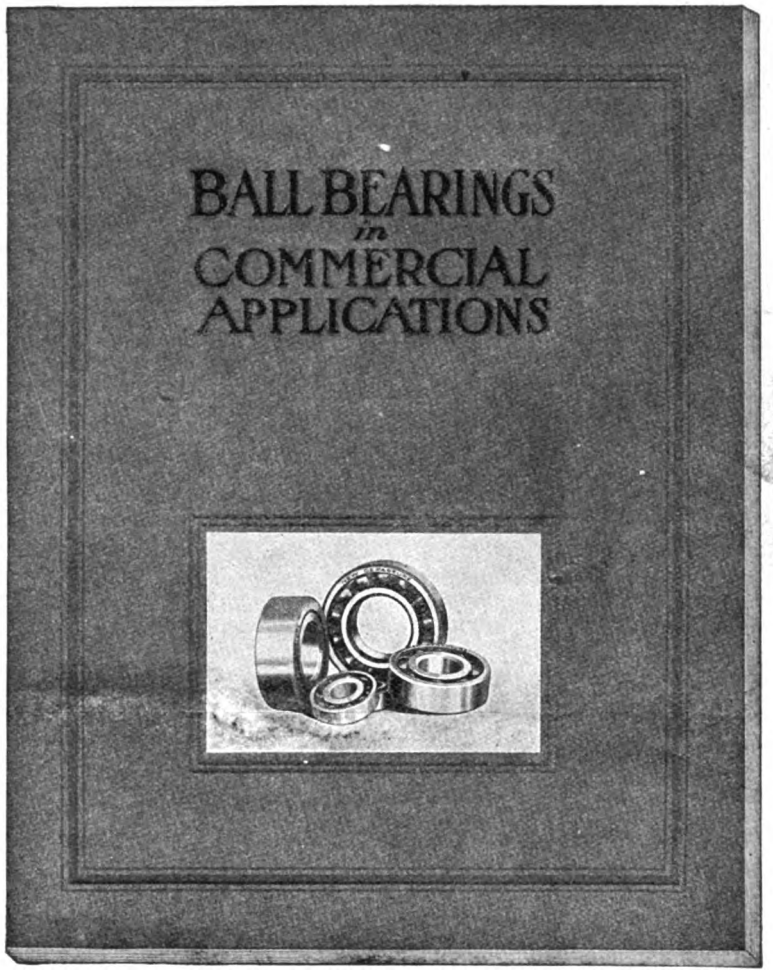
The Litl Sho-Fur.

This is the trademark name for a new device which has been brought out by the White Mfg. Co., 713-715 Main Street, Cincinnati, Ohio, and which is illustrated herewith. This device may be attached to any Model T Ford car without any machine work or even the boring of a hole. A pair of pliers or wrench to tighten the nuts is all that is necessary to apply it, and anyone can put it on a car in ten minutes. It attaches to the front axle of the car by means of two strap bolts. The two-leaf spring of specially tempered spring steel passes through the eye clamped on the tie rod. When the tie rod which connects the front wheels is moved to either side the

Plan View.

spring tends to return, center, or bring the rod back to its normal position. This is a safety device which will appeal to every driver of a Ford car. In turning corners, it straightens the car up without effort after the turn. It also helps to steer the car all the time, and holds the car in a straight line on the road when going at high speed. It does away with the wobble of the steering wheel, which sometimes causes a dangerous side sway even at moderate speed. It also prevents skidding to a large degree, and takes away the rattle of steering connections, tie rod, ball and socket joints, etc. It absorbs road shocks which would otherwise be carried to the driver's wrists, and prevents that tired feeling that comes after long drives. We understand that this device is moderate in price, and any of our readers who may be interested should write for prices and full particulars to the manufacturers at the above address.

The Cleveland Spring Cranker.



This is a new device especially made for starting Ford cars from the seat. It is designed and manufactured for Ford cars, and sold to Ford owners through the dealers, under the manufacturer's guarantee for one year. The device is simple and inexpensive, yet it does the work perfectly, and any reader who may be interested should write for full particulars direct to the manufacturers, the Forest City Electric Company of Cleveland, Ohio.

Cigars on Trial.

Every lover of a good cigar should turn to the advertisement of Herbert D. Shivers, 21st and Market Streets, Philadelphia, Pa., on another page and read his remarkable offer. He will send you fifty of Shivers' Panatelas on approval and pay the express charges without the payment of any money on your part. You can smoke ten of these cigars to see whether you like them or not and return the other forty at Mr. Shivers' expense if you don't like them, and no questions asked. If you do like them, you send him the price of the box of cigars. Of course, it goes without saying that Mr. Shivers, who has been making cigars for a quarter of a century or more, could not afford to make an offer of this sort unless he felt sure of the quality of his goods. It is coming along towards the holidays when a box of good cigars to a friend is always an acceptable present. When you order the fifty Panetalas referred to, ask for Mr. Shivers' booklet which will give you further particulars about the great variety of other cigars which he carries; some sold in boxes of 25. State the brand that suits you best, mild, medium or strong.

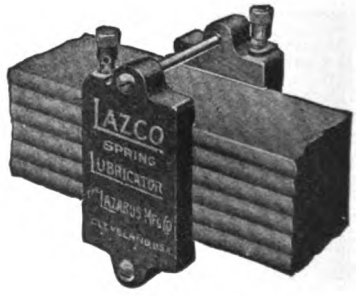
LAZCO
ENGINE TROUBLE DETECTOR

American and Foreign Patents Pending

Dial Actual Size

"More necessary than the speedometer, more useful than the clock"

Fulfills a positive need in the convenience and economy of motoring. With the Lazco Detector you can quickly locate and determine engine trouble from the dash, without raising the hood. Misfiring cylinders, carbonized or broken spark plugs, faulty ignition, cylinder knocks, battery and magneto difficulties, loose connections, lack of compression, etc., are simply and conveniently investigated and determined with the aid of this ingenious device. No complicated connections. You can install it yourself. The dial is quickly attached to the dash—boring one ¾" hole through which to pass the motor connections. The ONLY DEVICE of its kind and purpose. No motorist can afford to be without one. Shipped complete with all attachments and instructions.



Price Complete $5.00

Order through your dealer or direct.
Full Information, etc., on Request, Dept. R.

LAZCO Products

	PRICE
Engine Trouble Detector	$ 5.00
Lazco Vulcanizer	1.50
Lazco Spring Lubricator (4 Pairs)	2.00
Lazco 2-in-1 Vulcanizer (Large Size)	2.50
Lazco Fire Extinguisher 22'	2.00
Lazco Fire Extinguisher 12'	1.00
Lazco Repair Rubber, 1 lb	1.75
Lazco Electric Vacuum Cleaner	21.50

THE LAZCO VULCANIZER

For Casings and Tubes to 3½" Size, especially adapted for Ford Sizes, a smaller type of our well-known 2-in-1 Vulcanizer—effects perfect vulcanization, either tubes or casings. Automatic in operation. Enclosed flame, safe and sure—in the garage or on the road. Repairs casing cuts while tire is inflated. Complete with roll of Lazco Repair Rubber and instructions. Price $1.50.

DEALERS

The Lazco Line offers every advantage to dealers. A wide range of meritorious products—priced right and liberally discounted to the trade.

LAZCO SPRING LUBRICATOR

Cushions the jars, kills the squeaks, minimizes breakage and prevents rust. Automatically distributes the oil evenly and slowly between each leaf of your spring—simple—compact—efficient and easily attached to any make of car.

Full Equipment, PRICE $2.00 (set of eight—4 pairs).

The Lazarus Manufacturing Company, Dept. R

752 Euclid Avenue, CLEVELAND, OHIO

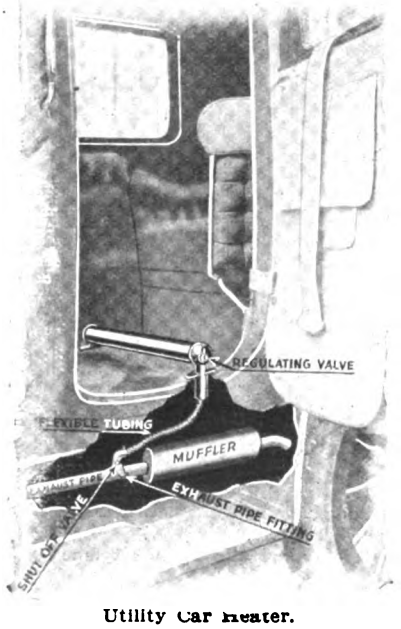
Garage Repair Sets.

Wiley & Russell Mfg. Co., Greenfield, Mass., make a repair set of taps, dies and reamers, especially for Ford cars. This assortment of taps, dies and reamers has been selected to meet the demand from garages and repair shops, and is based on their experience in handling repairs on Ford cars. The tools are



Made by the Wiley & Russell Mfg. Co., Greenfield, Mass.

of the celebrated Lightning quality which has been in the front rank for nearly 45 years. The price of this set of tools is low considering its quality.

A New Car Heater.

The Utility Car Heater, made by the Hill Pump Valve Company, Chicago, Ill., keeps the car heated at comfortable

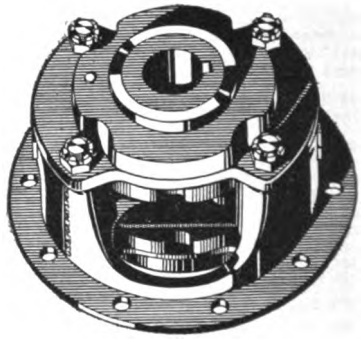
Utility Car Heater.

temperature in coldest weather without costing a cent for maintenance. The Utility Heater is a radiator and footrest combined and it utilizes the hot gases from the engine exhaust. The gases, instead of being wasted, pass through the heater when it is in operation and escape into the air beneath the car. The temperature is kept at the desired point by means of a regulating valve inside the car. It gives off no obnoxious odors or gases, and cannot burn anything, and can be permanently installed in half an hour. Garages and accessory dealers can make money pushing the sale of this heater at this time of the year, because if the heater is used it will make it possible for cars to be used all winter, thus giving them an opportunity of furnishing other supplies.

A New Book on Springs.

A book prepared to answer hundreds of inquiries regarding one point or another about automobile springs has been brought out by the Detroit Steel Products Co., of Detroit, Mich. This book is entitled "The Springs on Your Car." It is written by an engineer who has the gift of making himself understood by the layman, and we understand that it will be sent free of charge to parties who are really interested in this important subject.

Detroit Double Service Tires.



This is a tire which the manufacturers state is absolutely puncture proof. There is a double thickness of rubber and of fabric to protect the tread, and these tires are not made by merely stitching a fairly good casing over a hopelessly worn tire. Both casings are good and they are joined by a special process of vulcanizing, reinforcing, and heavy lock stitch sewing, making what the manufacturers characterize as a "peach of a tire," puncture proof, strong, oversize, and very durable. Readers are urged to write for prices and full descriptive matter to the Detroit Double Service Tire Co., 950 Woodward Avenue, Detroit, Mich.

Socket Wrench Sets.

The Packer Auto Specialty Company, People's Gas Building, Chicago, will shortly place upon the market a very complete line of socket wrench sets. This line will comprise the following sets: No. 6, in canvas case with glove button fastener flaps; No. 6A, in fibre case with flaps; No. 11, No. 22, No. 33, No. 39, No. 11a, special for Ford cars. In each of the above instances the number of the set designates the number of sockets contained therein. The No. 39 set will be most complete, having a complete assortment of socket wrenches, handle, long extension bars, five "S" wrenches, 8-inch drop forge Stillson wrench, combination screw drivers, short extension bars, cotter pin extractor, and other miscellaneous tools, making it what will be known as the "Universal Set, No. 39." A general catalogue featuring all of the above will be furnished upon application. This line was previously handled by the Fulton-McCutchan Company, who recently went into the hands of the receivers.

The Bailey Gearless Differential.

This article, which is illustrated herewith, ought to be interesting to a great many of our readers. The manufacturers claim that by the use of this device the motorist can laugh at snowy, sleety, slushy, slippery roads and drive any car in safety during the worst weather in winter. Thousands of car owners have installed it and thousands more will do so in the next few months. Ford, Overland and Chevrolet replacements in this differential are now ready for the market, and every Bailey gearless differential is sold on a guaranty of satisfaction or money back in thirty days. If you have this device installed on your car it is claimed that skidding, slipping and sidesway are absolutely eliminated. A positive drive is delivered to both rear wheels, and the power is only delivered to the wheel having traction. If you want your car to pull through roads which would ordinarily be

A New Differential.

impassable, it may be well to look up this invention, and dealers are especially urged to write to the manufacturers for their complete plan of co-operation. Address all inquiries to the Gearless Differential Company, 866 Woodward Avenue, Detroit, Mich.

Meco Engines for Garages.

There is nothing so handy for power in a garage as a good gas or gasoline engine, and the Meco engines made by the Manufacturers' Engine Company, 1879 Crystal Avenue, Kansas City, Mo., are especially recommended for this business. These engines are of a high quality through and through; they are of the center-firing, valve-in-head type, with automobile style ignition, also safety spark shift for easy and safe starting, without cranking. The best of materials and workmanship are used in all these engines with up-to-date fuel-saving design. They are simple to operate and durable under the hardest wear, giving even speed and continuous power. They are not only adapted for power in the garage, but many dealers and garage owners who read this publication can successfully act as agents for this engine, which is offered to dealers at an excellent profit. Readers who are interested should write direct to the manufacturers for full particulars.

Ball and Roller Bearings.

Many garages and repair shops are finding considerable difficulty in obtaining supplies of ball and roller bearings owing to the great war in Europe, and many of these will be interested to learn that a particularly large stock of bearings of almost every description is carried at the present time by the Gwilliam Company, Broadway and 58th St., New York City, N. Y. Their stock includes Annular Ball Bearings, Ball Thrust Bearings, Ball Thrust Step Bearings, Journal Roller Bearings, Pressed Steel Bearings, Roller Thrust Bearings, Taper Roller Bearings, Thrust Bearing Retainers, also brass, bronze and steel balls. Correspondence is invited from any of our readers, as this company may be in a position to deliver goods which cannot be found elsewhere under the present peculiar conditions of the trade.

Acme Cylinder Grinder.

The Acme Grinder Company, Minneapolis, Minn., is offering the Acme cylinder grinder, which consists of a base which is bolted to the face plate of the lathe, the cross slide to which the spindle is securely fastened, and the rotating sleeve which carries the grinding wheel. The construction is claimed to permit the wheel to rotate in a perfect circle, the diameter of which is regulated by means of a cross feed screw.

New Ignition Lock.

The Novelty Distributing Agency, South Dearborn Street, Chicago, is marketing a keyless lock for protecting the ignition system. The lock is circular in appearance and is fitted with sixteen buttons and in order to open the lock it is necessary to press a certain number of buttons at the same time. If other buttons are pressed while the combination is worked, the lock will not open.

Luminous Match Box.

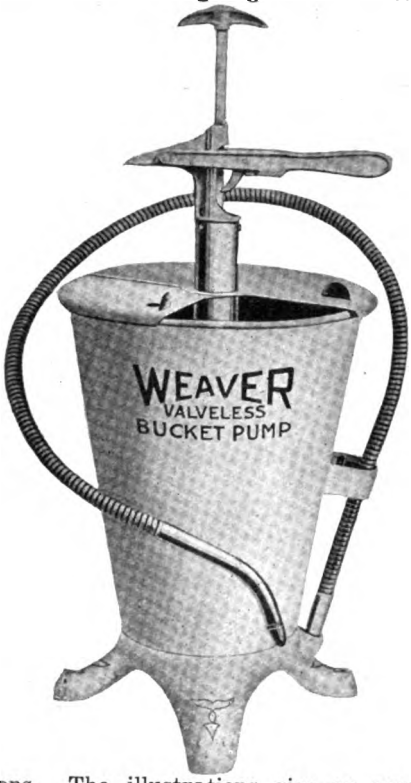
The Pioneer Portrait & Picture Frame Co., 1249 West 63rd Street, Chicago, has brought out a match box, which, when in a dark room, will give off sufficient light, because of a certain preparation with which it is coated, to allow of the person entering finding the box. This article can be used to advantage in private garages which do not use electric light with a switch in a convenient place. The box may be placed anywhere in the garage and upon entering the owner can see the box without much difficulty.

Radio Heater.

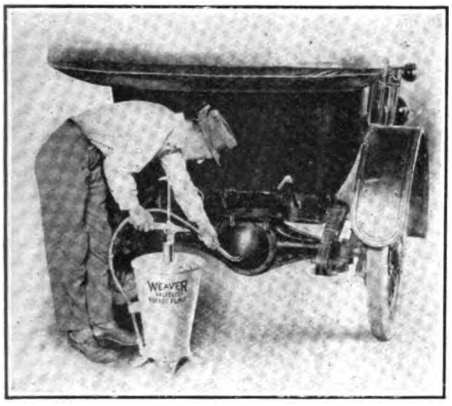
The Milwaukee Auto Specialty Company, Milwaukee, Wis., is manufacturing a heater which uses exhaust gas. This heater is connected in series with the exhaust pipe and when desired a portion of the exhaust gas passes through the heater and after giving up most of its heat passes out into the air. The Radio, as it is called, may be mounted flush on the floor-boards.

Ideal Fuel Saver.

More power and better fuel economy are said to be obtained by the use of the Ideal gasoline saver, manufactured by the Ideal Mfg. Co., 1525 Main Street, Anderson, Ind. This attachment is in the form of a fuel preheater which employs the heat around the exhaust pipe for warming the ingoing gasoline. The fuel line is tapped and a pipe directed to the heater which is clamped to the exhaust pipe, as shown herewith. The fuel after becoming heated passes to the carbureter. The price is $3.50.



Ask Gasoline Price Investigation.



Request has been made of the federal trade commission to institute an investigation of charges that illegal practices prevail in the marketing of gasoline. Price fluctuations have been brought to the attention of the commission which, it is declared, are not explained by the difference in freight rates between the cities where the varying prices exist.

The Weaver Valveless Bucket-Pump.

This is a very handy device for handling lubricants in garages and oil stations. The illustrations give an excellent idea of the appearance of this article.

Pump in Use.

The bucket is of ample capacity and is very substantially built to withstand the abuse which articles of this kind are likely to receive in the shop. The bucket is also equipped with a flexible steel hose which is of great advantage as ordinary rubber hose is soon affected by the action of the grease, while the metal hose is absolutely immune to anything of this kind. Another point is the "Three-Way" feature which makes it possible for the grease and oil to be drawn out of the car and discharged into another receptacle without disturbing the grease contained in the bucket. The ample diameter of the cylinder or barrel and also of the hose enable this bucket to successfully handle anything from light oils to soft greases. Garage owners or others who may be interested should write for further particulars and prices direct to the manufacturers, the Weaver Manufacturing Co., 2167-2179 South Ninth Street, Springfield, Illinois.

Pump in Use.

More Space for Firestone Plant.

Contracts have been placed by the Firestone Tire & Rubber Co., Akron, O., for additional floor space amounting to 110,000 square feet, nearly three acres. This amount is in addition to the five wings begun last spring and which are now nearing completion. A total of 10 acres of floor space has been added this year. This will allow an expansion in the tire output from 7,500 tires daily to 12,000 per day, an increase of 60 per cent.

Overland Tire Locks.

New Era Spring & Specialty Co., 864-878 Woodward Avenue, Detroit, Mich., the sole agents for the W. W. Sly Manufacturing Company, have had such a success in the marketing of Overland tire locks that they are now furnishing a form of this same lock that is made in the reverse position with small holes drilled so that the same can be riveted to the carrier furnished as standard equipment upon the Buick, Dodge, Maxwell, Oakland and other cars. The new form of lock is riveted to the lower part of the rim tire holder equipment which comes on these cars. The tire merely rests on this rim, being securely locked so that same cannot be taken off unless the rivets are broken, which can be made so this is practically impossible. The lock is furnished in the reverse position of the Overland tire lock and with the holes drilled without extra charge. The list prices are $1.50 for the single and $1.75 for the double.

Will Regrind Your Cylinders.

The Allen and Curtiss Co., Mishawaka., Ind., make a specialty of regrinding cylinders for the trade or individual motorists. Their scale of prices is as follows: 1 Cylinder, $12.50; 2 Cylinders, $17.50; 4 Cylinders, $25, and these prices include new pistons and rings. The work is absolutely guaranteed, and this company has facilities to do it promptly. Correspondence from our readers in regard to this work is solicited.

A New Carburetor.

The Penberthy Injector Co., of Detroit, Mich., has secured the rights for the Ball & Ball Carburetor in the United States and Canada, and we understand that this carburetor will be manufactured on a large scale. F. H. Ball and his son, F. O. Ball, who were for many years connected with the Ball Engine Co., of Erie, Pa., have been retained by the new company as engineers.

Ever See A Picture Of This Cigar Before?

Honestly, we believe that we could leave the signature off this advertisement and nearly half the men who saw it would know that it was put out by Herbert D. Shivers, Inc., of Philadelphia.

That is because the same cigar and the offer that follows below have appeared constantly for fourteen years.

Fourteen years is a long time. It is an *impossible* time for any cigar to be sold that is not an exceptionally good cigar at an unusually low price.

For fourteen years the Shivers Panatela has maintained the same quality, the same uniformity, the same flavor, the same mildness. Every tobacco man knows that the most trifling change, even in the color of a package, may wreck the sales of a product—so fickle is the public's favor in tobacco.

Yet for fourteen years we have claimed that our Panatela at $5.00 per hundred was the equal of the 10c or three-for-a-quarter cigar sold by "the trade."

We have repeatedly offered to take back any box that did not convince the smoker of this fact, pay all expenses and no charge for the cigars smoked; and our business has grown every year. Our customers have increased. We have been forced to move to larger and larger quarters—**and still we grow.**

Aren't you ready at last to try this cigar? Hasn't it earned its right to your recognition?

OUR OFFER is: Upon request, we will send fifty Shivers' Panatelas, on approval, to a reader of *The Automobile Dealer and Repairer*, express prepaid. He may smoke ten cigars and return the remaining forty at our expense and no charge for the ten smoked if he is not satisfied with them; if he is pleased with them and keeps them, he agrees to remit the price, $2.50, within ten days.

Selling direct from our factory to the smoker is the economic reason why we can offer a hand-made cigar with a selected long Havana filler, and a Sumatra wrapper, for $5.00 per hundred or $2.50 for 50. All our sales are by the box. The majority are on re-orders that come in year after year.

The Panatela is not our only cigar. We make seventeen different shapes, many of them clear Havana cigars. **Our complete catalog mailed on request.**

Read that offer again and see if you don't think it's about time you "took us up."

In ordering, please use business stationery or give references and state whether you prefer mild, medium or strong cigars.

High-Service Repair Parts.

Dealers in automobile supplies, agents for Ford cars, garages and repairmen should be especially interested in the High-Service repair parts for Ford cars which are made and sold by the Hill-Smith Metal Goods Co., 88 Pearl Street, corner High Street, Boston, Mass. They have over 300 repair parts for the trade, and they are continually adding to the number. The list includes rear axle shafts, differential drive gears and pinions, front and rear springs, nuts, bolts, keys, gaskets, bushings, screws, pins, ball bearings, connecting rods, front radius rods, washers, etc. This company has a price list which may also be used as an order blank. Write to-day for a copy of this price list and you will not regret it.

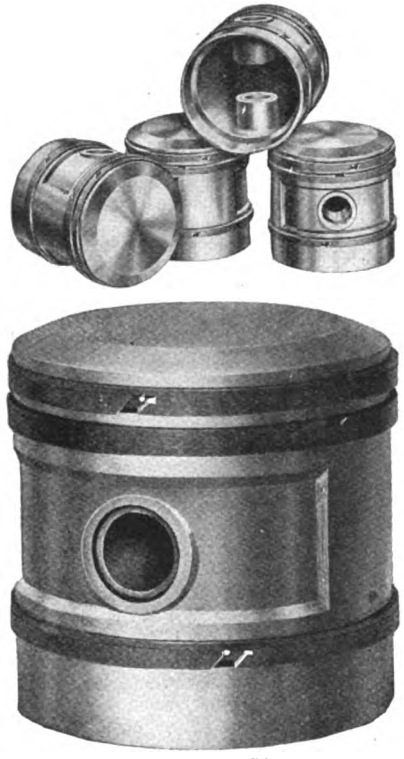
MOTOR VEHICLE PUBLISHING COMPANY.
F. R. WHITTEN, Secretary.



Sworn to and subscribed before me this 17th day of September, 1915.

[L. S.] (Signed) HARRY F. REISS, Notary Public No. 72.

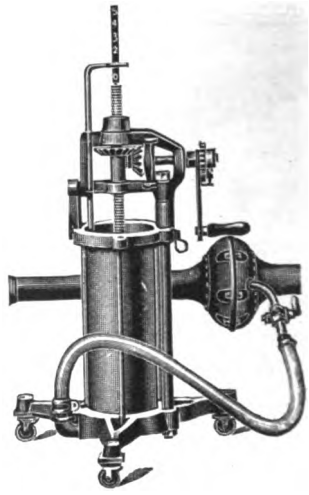
(My commission expires March 30th, 1917.)

Aluminum Alloy Pistons.

The adoption of aluminum alloy for use in pistons in a large number of the high grade motor cars for 1916 has brought about a demand on the part of Ford owners for a similar type of piston suitable for their cars. In response to this demand the McQuay-Norris Manufacturing Co., St. Louis, Mo., makers of the well-known "Leakproof" piston rings, is now announcing a die-cast aluminum alloy piston, completely equipped with "Leakproof" piston rings and suitable for Ford cars. An equipment of Lynite pistons completely fitted with "Leakproof" rings makes a very desirable installation from every point of view. Four Lynite pistons with twelve "Leakproof" piston rings packed in a box ready for installation will sell for $30, and since the "Leakproof" ring equipment for a Ford car formerly cost $18, it is obvious what an attractive price the combination can be bought for. This set can be installed by the Ford owner himself for the rings will be perfectly fitted to the pistons in the factory before going out, and it will only be necessary to take the old pistons out and slide the new ones in.

Lynite Alloy Pistons.

Elected a New President.



At the annual meeting of the Board of Directors of the New Departure Manufacturing Co., Bristol, Conn., Mr. DeWitt Page was elected president of the company. He has been identified with this concern practically since the first day of its existence. He came to Bristol from Hartford 23 years ago, and accepted a minor position, and he was rapidly promoted from one department to another, serving as paymaster, purchasing agent, and advertising manager. About ten years ago he was elected secretary and entered the Directorate of the company. In December, 1913, he was unanimously elected general manager of the Company. The selection of Mr. Page for the head of one of the most important manufacturing concerns in New England shows the confidence of his associates in the abilities, methods, and policies which have marked his general management of the company's affairs, and the New Departure Manufacturing Co. certainly deserves to be congratulated.

Another Victory for Norma.

On every winning car in the Astor Cup Race of October 9, ignition apparatus was equipped with Norma Ball Bearings, which is in itself very strong testimony in favor of these bearings. Norma bearings are made for magnetos, lighting generators, and starting motors, and for almost every purpose where ball bearings are required. Readers who are interested should write for their catalogue to the Norma Company of America., 1790 Broadway, New York City, N. Y.

The Ekern Portable Garage Grease Pump.

This is a grease pump especially made for public garages, and it certainly fills a long-felt want. All you have to do when a customer comes in and wants his car greased is to remove the plug in the gear case, insert the nozzle of the hose pipe connected with this machine and turn the crank, and the grease is forced into the gear case. The indicator on the machine will show the exact number of pounds of grease, or if liquid oil is used, it will show the number of pints put into the gear case. The pump holds 18 pounds of grease and can be refilled very easily. This is an article which will soon pay for itself in any up to date garage. The list price is $35 and the dealers price $23 with 5 per cent. discount for cash accompanying order. Send your orders and inquiries direct to the manufacturers, Ekern Bros., Flandreau, S. Dak.

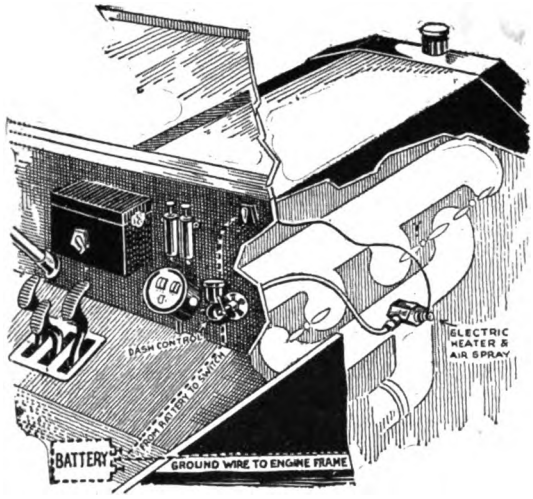
5-Year Guaranty

Here is a fast seller at the retail prices shown at the left. Our liberal dealer's discounts from these prices make you a good profit. Complete line of sizes and styles as here listed. With this agency, you can do the engine business of your trade territory. Write us now while your territory may still be open.

Sell This Engine



IECO ENGINES
Gasoline, Kerosene & Gas

Through and through high quality. Center-firing, valve-in-head type, with automobile style ignition. Safety spark-shift for easy and safe starting, without cranking. Best of materials and workmanship, with up-to-date fuel saving design of engine. Simple to operate, and durable under the hardest wear, giving even speed and continuous power.

Sold on Trial Every engine fully guaranteed for durability, capacity and all around efficiency. Write for our dealer's proposition under which you can handle this line without risk under our buy-back-in-90-days selling plan. Let us show you the profit in this agency.

Manufacturers Engine Co., 1579 Crystal Ave., Kansas City, Mo.

Start Quickly On Cold Days

Any morning nowadays it's a case of a cold motor—and crank, crank, crank, and prime, prime, prime before you can get it started.

IECO ELECTRIC MANIFOLD PLUG

will eliminate your starting troubles. We say it will. Your money back if it doesn't. The principle is simple. A few drops of gasoline into the priming cup on the dash. No lifting the hood, mind you. Then turn the motor over and - bing!—away she goes. The priming charge has passed through the Manifold Plug which contains an electrically heated coil and has entered the cylinders perfectly evaporated, ready to explode at the first spark. Current is only used while starting. Another thing, it admits auxiliary air to the manifold, saving 20 to 30% in gasoline. Can also be used to introduce kerosene into the cylinders, clearing them of carbon.

PRICE, $5.00. IN CANADA, $7.25.

(When ordering specify voltage of battery—Ford cars require six dry cells.)

DEALERS: Ieco Manifold Plugs and Steer Warms are the biggest hits of the year. They are sweeping the country like wildfire. You cannot afford to lose these ready sales. Write today for our dealers' proposition.

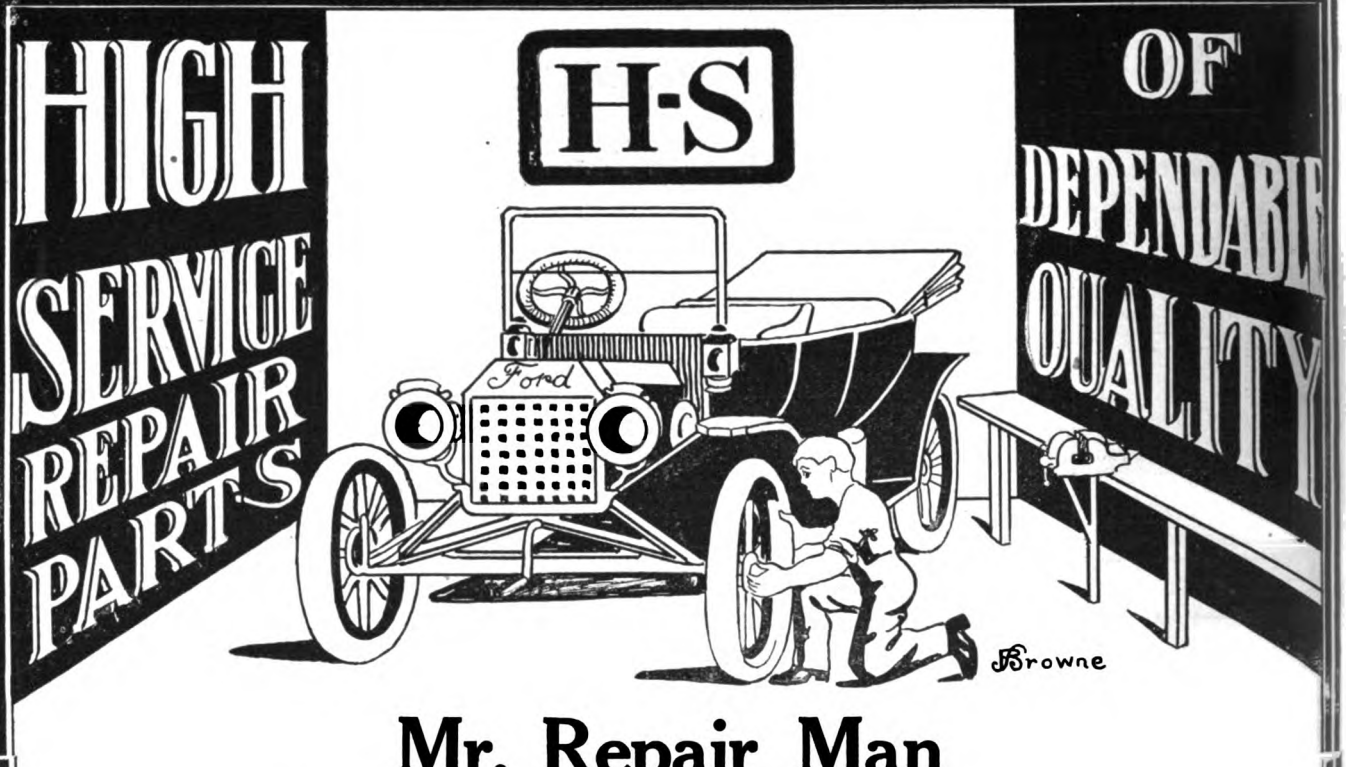
INTERSTATE ELECTRIC CO., 845 Perdido St., New Orleans, La.

Increased Production Makes Lower Price.



Always in line on modern merchandising and manufacturing, A. R. Mosler & Co. has again established a precedent in announcing a startling price reduction on their Vesuvius spark plug. Increased production and factory efficiency only make this possible, and this in the face of a rising market on raw materials. The Vesuvius is standard equipment on such quality cars as the Pierce-Arrow, Simplex, Locomobile, Jeffery and Case, with a record of unparalleled service behind it. It is authoritatively stated that this price reduction is but the first shot in a tremendous drive on the Vesuvius, in the knowledge that the automobile owner of today recognizes the value of quality merchandise when the seal of the manufacturer's engineer has been put upon it.

Ottofy Heater.

This is of the type which uses exhaust gas to heat the car compartments. The exhaust manifold is jacketed and the jacket extended to the car compartments where it is attached to registers in the floorboards. The hot air from around the exhaust pipe and portion of the manifold is sent through the system to the registers and thence through the compartments. The maker is the Ottofy Motor Car Co., 3040 Locust Street, St. Louis, Mo.

Mr. Repair Man

Comparison and trial will convince you that our

HIGH-SERVICE REPAIR PARTS

are noticeably superior in fit, finish and material. They will furnish the maximum wear, and will make a satisfied, regular customer, of any one on whose Ford car you install our parts.

The more than generous discount we allow enables you to get our High-Service Repair Parts at a price so low you can make a greater profit handling them, enabling you to save money on your purchase price, and make more money on your sales, or repairs.

Dealers of Auto Supplies, Ford Agents, Garages, and Repair Men, should be especially interested in our High-Service Repair Parts for Ford cars. Full credit allowed for any part returned as unsatisfactory for any reason.

Rear Axle Shafts Differential Drive Gears and Pinions Front and Rear Springs
Nuts Bolts Keys Gaskets Bushings Screws Pins Ball Bearings
Connecting Rods Front Radius Rods Washers, Etc.

We have over 300 Repair Parts and are continually adding to the number. Our price list is also an order blank.

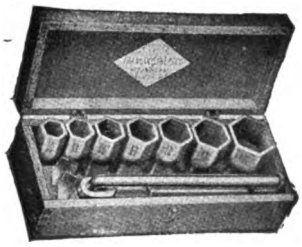
Note: 1620—Tomahawk may be used in place of 3240, the only advantage, the socket on end is used in spinning nuts off or on. On several parts more than one wrench is listed. The offset gives longer leverage. The tee handle or brace may be more efficient.

The most complete line of Wrenches for use on Ford Cars. All steel—guaranteed tools.

Our directory of wrenches for use on Ford Cars is the result of having actually tried out each wrench on the part named to insure proper clearance around the nut, and working space for the handles. The object to obtain full efficiency for the tool, and use of the same wrench on as many different parts as possible.

Our original designs have been copied but none of the imitators have yet covered all the fine points in design. Your protection is to look for the name **WALDEN-WORCESTER** stamped on every wrench and box. Do not accept substitutes.

There are no "come backs" on **WALDEN-WORCESTER Wrenches.** They are absolutely guaranteed to you and user. Get permanent profits and good will by selling real tools.



If your dealer or jobber does not carry these tools, advise name and we will ship, charges prepaid, on receipt of price.

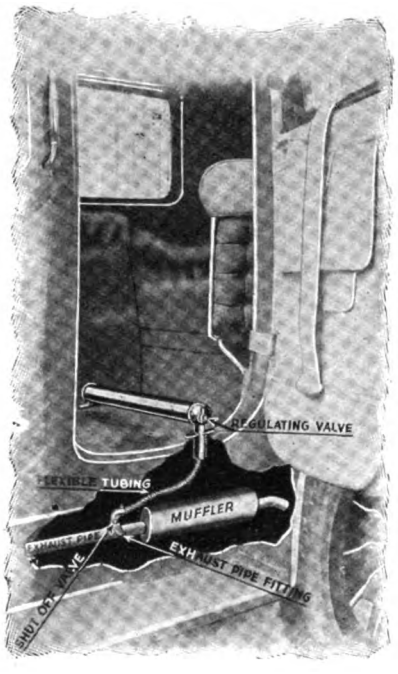
Keep Your Customers All Winter

By pushing The Utility Heater, which is adaptable to all Gasoline Cars.

Bringing to Automobile and Accessory Dealers



All the fair weather riders, making them all the year 'round callers on you for Supplies and Accessories.

ALL WHO USE THE UTILITY HEATER

Which is a radiator and foot rest combined, that will make any automobile comfortable during the cold winter days.

This device is so economical to operate, using only the hot gases from the engine exhaust. These gases, instead of being wasted, are used to increase the efficiency of your automobile, keeping it at an even, comfortable temperature at all times. A valve, easy of access inside the car, regulates the temperature instantly.

At the same time increase your sales by handling this simple, ornamental and indestructible heater, which is easily installed, making it necessary to drill only three small holes, two in the bottom of the car, and one in the exhaust pipe in front of the muffler, and can be done in half an hour.

This Utility Heater is also a handsome addition to the looks of your car, as it is fully nickeled.

We also make a Special Heater for Ford cars for $12.00. This heater is identical in every particular to the Utility Heater.

Get in on the ground floor before the other fellow.

Write us today for circular, terms and price.

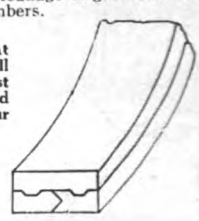
Good Business for Live Dealers



Many car owners would keep their cars in use for winter driving if they thought they could protect themselves against the power losses of cold weather and the winter snows.

K-P PISTON RINGS

offer a way. They give maximum power for winter's demands by utilizing the whole force of each fuel charge. They eliminate power waste by stopping all leakage of gas and oil in the combustion chambers.

"A Motor Is No Better Than Its Piston Rings." —*Efficiency Ed.*

Show the car owner that K-P Piston Rings will protect his motor against winter power losses and you will cash in on your arguments.

Special Inducements to Dealers and Agents.

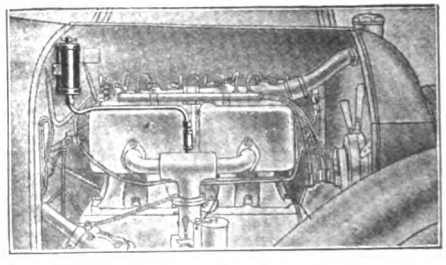
PATENTED Side Lock and Groove

STOP THAT LEAK

You are using too much oil!
You are wasting gasoline!
You are not getting enough power!
DON'T THE UP-KEEP GIVE YOU THE BLUES?

Trade Mark

Patent Applied For



There was a time when water pumps at the City water stations used a fabric or leather packing; not so today. A copper jacket is put in the cylinders. **Large grooves** are cut in the pistons, the volumes of water in the grooves form a packing, small particles of water cannot pass the volumes of water in the grooves. Thus making a perfect packing of water against water. Just so with "NO-LEAK-O" Rings. The volumes of oil in the grooves act as a packing against the oil being drawn or forced up into the firing chamber. "NO-LEAK-O" piston rings have grooves which CONTROL THE OIL, giving perfect lubrication without waste. No smoke. No carbon. No oily spark plugs. No grinding of valves. We absolutely guarantee each ring for QUALITY, ACCURACY and SATISFACTORY service. ONE PIECE, LOW COST, HIGH EFFICIENCY. Carbon eliminated by controlling the oil. *Write at once for complete particulars.*

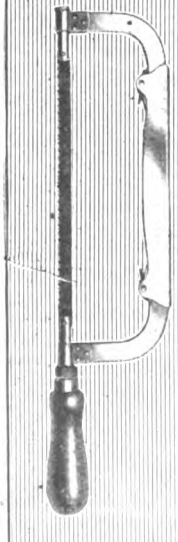
Handy Tools



TOOLS for the motorist must first of all be handy tools. There are many bolts that are almost inaccessible for the ordinary wrench but easily reached and turned with the **Starrett Ratchet Wrench.** This consists of a long handle into which fit wrenches of all needed sizes. The ratchet makes turning easy in the most cramped spaces.

Starrett

Expansion Pliers

may be used either as a wrench or pliers. The jaws give a grip so powerful that the tool can even be used as a pipe wrench. There are many uses for this tool about the garage or the home.

Starrett Hack Saws

cut faster, last longer and do cleaner work than most because of the high quality tungsten steel, the proper set and shape of teeth, the improved methods of manufacture.

Starrett Tools include 2100 styles and sizes.

Oxy-Acetylene Welding and Cutting

Welding steel rings 1¼ by ¼ inch at a cost of 5 cents each.

Make Added Profits By This Process

Manufacturers of automobile parts, metal furniture, racks, window sash, steel tanks, boilers, machine tools, laundry equipment, surgical apparatus and many other products have simplified construction and increased efficiency and profit through oxy-acetylene welding.

In some lines it has entirely displaced the rivet, resulting in higher quality at less cost.

Oxy-Acetylene welding makes added profits possible for you, by providing the best, quickest and cheapest method of metal joining.

The oxy-acetylene process is not limited to production work. It often more than pays for all needed equipment in time saved on repairs by repairing a single piece of broken or worn equipment, preventing tie-ups in production, delays and expense of replacement.

Necessary equipment is not expensive. We furnish high-grade apparatus for $60; Canada, $75; acetylene service at slight additional cost. Adaptable for oxy-acetylene cutting with the addition of special cutting apparatus. Thorough instructions are furnished free to every user of the Prest-O-Lite outfit. We will train your operators free if you desire.

Prest-O-Lite PROCESS

Employs Prest-O-Lite Dissolved Acetylene (ready-made carbide gas) in portable cylinders—backed by Prest-O-Lite Service. Used as conveniently as cylinders of oxygen. Saves large initial outlay and heavy depreciation of making crude acetylene in carbide generators. Perfectly dried, cleaned and purified—makes better welds and is cheaper to use.

Start Now—Get Full Details

Doing Oxy-Acetylene welding for others is a highly profitable business. The cost of equipment is low. Immense and growing demand assures profitable operation from the start. Even at very moderate charges, the profits from this end of your business are too big to be neglected. It is a good business opportunity for enterprising men.

The many possible uses for Oxy-Acetyline welding in your garage will surprise you. Oxy-Acetylene literature, thoroughly illustrated, sent free. Write your name and address on margin of this page and send to

National Rubber Tirefiller

Ends All Tire Trouble—A Perfect Substitute for Air

Made of Pure Rubber, cut in small particles, treated, moulded and vulcanized by our special steam process. Fits all the different size casings. No inner tube and air used, eliminating the cause of all tire trouble. Stops the expense of buying, repairing and replacing inner tubes. Doubles the life of the casings—reducing the cost one-half. Can be transferred and re-transferred as often as is necessary. Has all the easy-riding qualities of the air-filled tire, with none of its faults and uncertainties. No waiting to use your car; it is always ready whenever you need it. Let us send you small sample and tell you more about it.

NATIONAL RUBBER FILLER COMPANY
208 COLLEGE STREET - MIDLOTHIAN, TEXAS

MOTOR EYE
SEES ALL TELLS ALL

DETECTS MOTOR TROUBLE INSTANTLY

Flashes a warning of danger before the harm has been done. The motor is the car's most costly piece of mechanism and should be given protection commensurate with its importance. A ruined motor means a ruined car. $2.50 invested in prevention may save $100 expended in repair bills.

A radiator thermometer is the only known means for instantly detecting trouble beneath the hood of a running car.

READY TO ATTACH
$2.50

MOTOR-EYE is the cheapest motor insurance obtainable. Don't pay more for devices that won't do more.

Pin a money order to the attached coupon and get one of these little sentries out on your radiator cap keeping a never-tiring eye on what is going on inside. Money refunded if not satisfied.

Metal Cannot Wear if it is Constantly Protected with the Right Kind of Lubrication

TRADE MARK REGISTERED IN

NON-FLUID OIL

UNITED STATES PATENT OFFICE

is the ***only*** lubricant for bearings and gears which ***never fails*** to lubricate, because it never freezes and it never gums. In coolest weather your bearings are fortified against wear because the destructive rubbing and heating from friction is arrested and absorbed by the lubricant itself.

Get A Can Today And Prove It

The original NON-FLUID OIL is identified by orange-colored cans bearing the above sprocket-wheel trade mark. Avoid substitutes.

New York & New Jersey Lubricant Co.
165 Broadway, New York

"K No. 00 Special" grade for sliding gear transmission

Ford

owners stop the Big Noise

By Making Your Car as Quiet as an Electric and as

Sturdy as a Truck for Heavy Duty

DOTTED LINE shows the teeter and buckle as you step on your car now.
SOLID LINE shows how rigid CASEY braces are guaranteed to make it.

The strongest chain is limited by the strength of its weakest link. The weakest link in your Ford car is the step boards.

If you doubt this just step on your own Ford as a test and you will positively prove that the dotted lines here shown are not exaggerated but taken from an actual demonstration.

The solid lines in drawing clearly illustrate the most practical design for rigidity and strength, which follows the trusty principle of three point structural steel trussing as used in Bridge building and other permanent construction.

Two dollars, invested in a set of Casey Step Braces are not alone the first and only cost, but that they will positively support your Step Boards and Chassis as illustrated, besides eliminating this rattling from your Car during its entire life, we guarantee absolutely.

Any time you prefer to go back to the destructive Teeter Board, we will pay all transportation expenses and give you your Money Back, without a question.

Anyone can easily attach the Casey Step Braces in a very few minutes. No drilling or fitting necessary. All you need is a wrench. Shipping weight 4 pounds. Casey Step Braces complete, per pair..... **$2.00**

Our letter files have thousands of letters from pleased customers expressing exceptional satisfaction and service:

JENNINGS MOTOR CAR CO., JENNINGS, S. D., writes: "Express us at once twelve more sets of Casey Step Board Braces. We find them one of the very best things for Fords that have been put on the market."

H. W. GILL, PORTAL, N. D., writes: "Parcel post me two sets of Casey Step Board Braces, one I am ordering for a friend. Please thank 'Casey' for this valuable tip, and also the AUTOLOG."

J. M. MUILENBURG, HURLEY, S. D., writes: "I would not take $10.00 for my Casey Step Board Braces if I could not buy another set. They are worth more than ten dollars to any Ford user. I particularly show them to all my Ford friends, realizing how 'Casey' won my eternal gratitude, in giving my own car a more enduring and noiseless foundation for heavier service."

CASEY ASCO MANUFACTURING CO., 1500 Grand Ave., KANSAS CITY, MO.

For Leaky Cylinders

Superior to All Others

PATENTED AUGUST 6, 1912

A Piston Ring Which Gives Compression in "Out-of-Round" Cylinders as Perfectly as in True Ones

Here is a piston ring that gives 100% efficiency to every type of motor, engine, compressor or pump.

Ideally adapted to use in Automobile and Motorboat engines.

Gives compression when all others fail. No need to rebore worn cylinders—simply install EVER-TIGHT piston rings and the motor is good as new.

EVER-TIGHT piston rings are made up of three individual, interlocking rings, grooved together to give flexibility and reduce friction. This three-part construction is clearly seen in illustrations above. This is the only perfect three-piece piston ring on the market.

If dealers do not carry EVER-TIGHT piston rings, Auto repair men should write us.

Jobbers and dealers wanted everywhere. *Write for particulars.*

Do you buy Mileage?—or do you buy tires?

Take a look at this tire. There is a double thickness of rubber and of fabric.

Does it need argument to show why this double thickness of tread with the added strength gives you *more service miles?*

Get this idea—Detroit Double Service Tires are not made by merely stitching a fairly good casing over a hopelessly worn tire.

Both casings are good and when joined by our special process of vulcanizing, reinforcing and heavy lock stitch sewing the result is a "peach of a tire"—puncture proof—strong—oversize—and there with the wear. It is about as though a maker of standard tires were to *duplicate* his process of manufacture, so far as the tread is concerned.

When you get our prices and descriptive matter you will agree that in Detroit Double Service Tires you are bound to get *miles* of service, easy riding, absence of worry and no increase in gas consumption or upkeep expense.

Write for owner's price list—it gives full information. Ask for special prices on our red inner tubes.

Detroit Double Service Tire Co.
950 Woodward Ave. Detroit, Michigan

WITHERBEE BATTERIES

HEISER'S IMPROVED CYLINDER REBORING TOOL FOR FORD ENGINES

REPAIRMAN

There has been a period in your life that you were unable to tell a valve from a spark plug, a magneto from a carburetor, or a cylinder from a piston; some one had to tell you what these parts were and their function. The troubles arising from these and other parts of a car, you have mastered, but you are still at sea if you do not understand and are not prepared to rebore and fit oversize pistons, for this is the most important repair that can be given a worn engine.

The HEISER IMPROVED CYLINDER REBORING TOOL for Ford Engines, makes a good shop out of a poor one and a better shop out a good one, but best of all, it gives the owner service. The end of this season will see one million Fords on the highways; this means many million dollars will be spent on reboring and fitting oversize pistons.

The early bird catches the worm. We furnish oversize pistons to fit the rebored cylinder, $1.50 each, Complete.

Write for further particulars about this wonderful tool.

Safety First.

Without C-CLEER

Using C-CLEER

Is a Life Saver in Inclement Weathers. **SAFETY ALWAYS.**

C-CLEER completely overcomes one of the most dangerous condit ons which confronts the driver of a motor car, locomotive engineer, steamship pilot, motorman, etc.

"As Necessary as Skid Chains."

C-CLEER is a great necessity. How many times when touring would you give twice its price for a can of C-CLEER? For instance, when you get caught in a storm and it is impossible to see the road. Sticking head sideways means sickness and danger. By applying a little C-CLEER on the shield you will absolutely be safe and convenient.

C-CLEER does not collect dust; no breakage and no leakage, no liquid disintegration. It is satisfactory and economical.

Sold by RELIABLE DEALERS EVERYWHERE.

Price 25c per can. *Beware of Imitations.*

C-CLEER is packed two dozen to a counter display box. Dealers, write for discount.

MANUFACTURED BY
SOLE MANUFACTURING CO.,
258 Broadway, New York.

The McCormick Weatherstrip stops that leak thru your Wind-shield

The McCormick Weatherstrip is adjustable to any space or thickness of glass. Easily removed. Allows free movement of panes. Will not obstruct vision. Less than half inch wide.

THE ROBINSON MFG. CO.

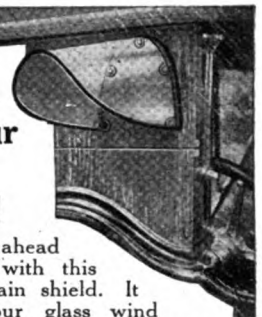
RADICO THE LEAKING RADIATOR COMPOUND



In fifteen minutes RADICO makes a metallic repair absolutely sure and permanent.

This compound contains no acids or other injurious minerals which would eventually corode the metal and cause other leaks.

MODERN SUPPLY HOUSES AND GARAGES CARRY RADICO.
Write for descriptive circular and price.

MANUFACTURED BY
RADICO MANUFACTURING CO., Box 887, Springfield, Mass.

Stick It On Your Wind Shield!

Clear view ahead at all times with this great little rain shield. It sticks to your glass wind shield with 5 vacuum cups. Strongest wind cannot blow it off.

U=CAN=C
TRADE MARK

Rain Shield

Made of tough, flexible, transparent Pyraline. Lasts for years. Attached to the glass in ten seconds. No water can run under or drip off the edge.

It Rolls Up!

Removed instantly by slipping penknife blade under each rubber cup. It rolls up and goes into the sturdy fibre tube when not in use. Tube is only 10½ x 3 inches. The finest and only rain shield.

By Mail for $1.50

Send $1.50 for one of these splendid rain shields on approval. Amber combination sun and rain shield, $2.00. Prepaid to any point in U. S. Money back if not satisfied. Worth ten times its price in every rain or snow storm. 50 cents extra in Canada.

Dealers: Write quick for agency proposition and prices. This is the fastest seller in the accessory line.

On your window sells itself. Goes on every car.

Write today.

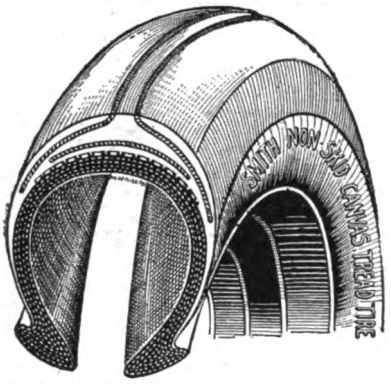
THE KING DRAG

The Great Road Builder

In every part of this great country the **King Drag** can be used to advantage on country roads for putting them into proper shape at a moderate expense. We have brought out a pamphlet which gives full particulars of the use of the **King Drag** and how to make it.



In localities where the sentiment for good roads needs to be worked up, the distribution of these little pamphlets could not fail to do a good deal of good.

We will send **a sample free of charge** to anyone desiring to see it, and will supply the booklet at **a dollar a hundred.**

SMITH'S NON-SKID CANVAS TREAD TIRE construction guaranteed for 5000 miles but average is 10,000 miles. Two strips of rubberized canvas projecting from the inside of the tread to the outside, makes this tread non-skid all the way through, and also acts as a radiator, preventing the tread from heating, peeling off. Also prevents stone bruises, punctures and blow-outs. It draws easier than tires with knobs on the tread and saves 25% in gasoline. **Free booklet describing other important features and agent's proposition.**

Atwater Kent
Ignition

What Is Your Opinion?

Friends of the magneto claim its superiority in its increased spark heat at high speeds (little being said of low speed performance).

Manufacturers of closed-circuit battery ignition devices claim an advantage over the magneto in producing a hotter spark at low speeds than at high.

Assuming that both are right—how much better is the Atwater Kent System, which produces an intensely hot spark, equally hot no matter whether the motor is cranking, idling or is running at seventy miles an hour?

Atwater Kent Ignition is different from all other battery ignition devices—being built on the simple open-circuit principle. Its success is due to its unique mechanical construction, on which basic patents are controlled.

Absolutely uniform spark heat at any speed, under any condition, is but one of many advantages which this remarkable system possesses over all other ignition equipment

Ten years of specialized scientific development concentrated on the problem of perfect ignition have resulted in Atwater Kent Ignition in its present form.

Thirty manufacturers, thousands of dealers and nearly 200,000 owners constitute the jury of award.

Atwater Kent Manufacturing Works
4937 Stenton Avenue, Philadelphia. U. S. A.

"F-S" EVERNEW Auto-Top Dressing

It won't crack in folding and is absolutely non-injurious to fabric.

It is easily applied and dries quickly to a durable, pliable, waterproof finish. Just the thing for leaky, moisture-holding mohair tops.

Eight standard colors—special shades to order.

"Evernew" Auto-Top Sizing for first coat on mohair, cloth or canvas tops that have never been painted.

"Evernew" Auto-Body Enamel in colors to correspond with our "Evernew" Auto-Top Dressing, including special shades to order.

You ought to have a supply on hand while doing the overhauling for next season. Write now for color card and prices.

Here's the One Best Way to Scrape Bearings

Better Work in ¼ the Time!

Consider the advantages a repair shop or service station would have if it could **ream** the bearings of four motors, doing a perfect job, while competitors were hand scraping one set with ordinary results.

Well, that is exactly what happens after a shop is equipped with a

MARTELL A-L-I-G-N-I-N-G REAMER

Because of the short time required for reaming, such a shop could afford to drop the price a little and still make more money per job. The lower price together with better work and speedier service would insure a monopoly of work in that vicinity.

This reamer insures absolute alignment of bearings, accurate size, perfect gear mesh, and produces truer, smoother bearings. No bother in scraping, taking prints, etc., as with the hand scraping method. Set No. 1 for bearings on all standard cars. Set No. 2 for light car bearings such as Ford, Metz, etc.

Send for free booklet—"**A Better Way to Scrape Bearings.**"

Reserve Artillery!

How we help the dealer "cash in" on The Big Push

Last month we announced our big campaign in the Saturday Evening Post and seventeen other national mediums.

It is the Big Push !—the strongest support ever given the automobile dealer in the sale of an article like Campbell Detachable Upholstery.

Now we announce the Reserve Artillery—the selling force we furnish our dealers so that they may convert the magazine-created demand for Campbell Detachable Upholstery into dollars in the cash drawer.

The beautiful display stand illustrated above is but one of the Big Guns. We give you in addition handsome posters in seven colors, booklets, etc., to follow up your trade and make sales.

Without any concentrated selling effort Campbell Detachable Upholstery outsells all other articles of interior trim for motor cars. But backed by the tremendous advertising campaign we are putting behind it, Campbell Detachable Upholstery is the livest accessory you can stock.

If you want to sell prestige, luxury that has no competition, and an article that is in a class by itself, that insures you against mail-order competition, write or wire for samples, prices and trade discounts on Campbell Detachable Upholstery and details of our co-operative selling plan. The Perkins-Campbell Co., 628 Broadway, Cincinnati, Ohio ; New York Office, 89 Chambers Street.

an instant Success

The trade wasn't long in getting onto a good thing. Orders for McQuay-Norris LYNITE Pistons, LEAK-PROOF Ring equipped, for Ford Cars, are coming in from all over the country.

Live dealers have realized the sales possibilities of the proposition. They know the biggest and easiest profits belong to the fellow who is stocked and organized ahead of his competitors when the demand sweeps in.

Think of those 700,000 Ford Owners on the lookout for this chance ever since aluminum pistons were first talked about. A ready-made market for you. Get the facts about our proposition—tell the Ford Owners around you about it—get their orders first.

The "Barefoot" Tire——

——and Why.

◆ ◆ ◆

WHEN you take your Shoes off tonight, do this:
—Bear your weight on your right Foot and, without lifting it off the floor, press it forward and backward firmly.

Then observe that only the bony and muscular *Structure* of your Foot *moves* forward and backward, while its *Sole* stays *fixed* on the floor.

That demonstrates the *rolling motion* of flesh and muscle, the elastic Cushion quality which *reduces friction* in walking, and prevents slipping (backward, forward, or sideways).

It supplies that CLING quality, which gives *Traction without Friction.*
